# RETROPUBIC PROSTATECTOMY

FRANCIS A. BENEVENTI, M.D.
and
FRANCIS P. TWINEM, M.D.
New York

We present an analysis stressing the high lights in uccessful retropubic prostatectomy in 40 cases done in a city hospital. From this series, in which a large percentage of the patients were poor risks, we were particularly impressed by (*a*) the smooth convalescence and (*b*) the appearance of the urethra and bladder neck after operation.

## HISTORY

Although the operation has been previously performed in this country [1] and in Europe,[2] it did not capture the fancy of American urologists until after June 1947, when Millin first demonstrated his operation in this country at the Brady Foundation in New York. The feasibility of the operation first became apparent to him during the course of radical cystectomy for carcinoma of the bladder.[3] In removing the bladder transabdominally, he saw no reason why the prostate and seminal vesicles could not be extirpated at the same time without an additional operation via the perineum.

## HEMOSTASIS AND STUDY OF BLOOD VESSELS

A knowledge of the distribution of the blood vessels in this area is necessary for hemostasis. After the peritoneum and retropubic fat have been gently retracted upward away from the symphysis pubis and the prostatovesical junction, a large central vein can be seen arising from a point just underneath the arch of the symphysis pubis and taking a course cephalad over the midportion of the prostate and bladder neck. This vessel is called the superficial branch of the deep dorsal vein of the penis and should be ligated. When ligated, it is apt to give the surgeon a false sense of security, if he feels that the principal vein has been eliminated. In some cases this vein can be retracted laterally out of the field of incision into the prostatic capsule without preliminary ligation. Inasmuch as the veins in this region are large and extremely thin walled, they should be handled and retracted with great care in order not to rupture them. These vessels lie in the folds and layers of the endopelvic fascia, and the distribution of the smaller branches over the anterior aspect of the prostatic capsule varies considerably. When these small branches assume a vertical course over the prostate, some surgeons use the vertical capsular incision in order to avoid injuring them. The formation of the principal veins of this region is contributed to by the two plexuses of veins at the obturator foramen exterior to the obturator internus muscle, by the pudendal plexus and by the deep dorsal vein of the penis. The latter is the principal and most important contributor. As the deep dorsal vein of the penis enters the pelvis after penetrating the urogenital diaphragm it trifurcates into right and left lateral branches and a superior branch which has been previously mentioned. The lateral branches become a mass of large thin-walled veins which hug the lateral aspects of the prostate, prostatovesical junction and the lower portion of the bladder (fig. 1). These constitute what we have referred to as the lateral plexus of the prostate. Inasmuch as these plexuses are so dense and thin walled, it is wise not to use suture ligatures for the control of bleeding from this area. Such bleeding occurs after rough handling and after one has extended a transverse incision laterally incident to delivering a massive gland. Whenever these vessels have been opened it has been our policy to pack the bleeding area rather than resort to ligation or electrocoagulation.

The principal arteries of surgical consideration in this area are branches from the hypogastric or internal iliac artery. It gives off the inferior vesical paired arteries which enter the prostatovesical junction at the lateral and lower aspects of the bladder neck (at 5 and 7 o'clock, fig. 1). Before entering the prostate, these vessels give off smaller anterior capsular arteries which pass over the anterior aspect of the capsule and present no problem in ligation. Ligation of the inferior vesical arteries is carried out under direct vision after the prostate has been enucleated. A mattress or figure of eight suture taken at 5 and 7 o'clock of the bladder neck does this easily, and at the same time they can be made to plicate the bladder neck when the latter is redundant. It has been our practice to apply these sutures whether or not the open ends of the vessels are seen. In one of our earlier cases, we saw no open vessel in this region and consequently used no suture. The patient was returned to the operating room because of secondary bleeding twenty-four hours later. After the blood clots had been removed from the prostatic fossa and the bladder, we discovered the feebly spurting open ends of the inferior vesical arteries at the bladder neck. This has been our only instance of secondary bleeding. It might be well to mention that the secondary operation was done via the retropubic

route; the bladder was evacuated of clots through the neck of the bladder. This exposure alone could afford the excellent view of the vessels at the neck of the bladder.

PROSTATECTOMY

Before opening the capsule (fig. 2), one places two or three chromic sutures well into the true and false capsules of the prostate at the most distal accessible portion, at the same time underrunning any visible veins. These sutures are tied and left long. Incision into the anterior capsule has been done transversely in all but 3 instances when a vertical incision was used.

Fig. 1.—Study of the arteries and veins of the retropubic region and the anterior portion of the prostate and the bladder. *A*, view from above. The bladder is shown drawn upward, exposing the anterior surface of the prostate, the puboprostatic ligaments and the artêries and veins of the prostate, symphysis pubis and anterior wall of the bladde. *B*, side view showing the bladder drawn upward; the prostate, puboprostatic ligament (etc.) in relation to the veins and arteries of the prostate, symphysis pubis and the anterior wall of the bladder.

Our preference for the transverse incision is based on the fact that it affords better exposure of the bladder neck. In 3 cases, retropubic prostatectomy was carried out in two stages, cystotomy being necessary to empty the distended bladder of blood clots and urine. After the capsule is opened down to the adenoma, the line of cleavage between the prostate to be removed and the false capsule is followed down to the apex of the gland. When the lateral aspects have been freed, the apex is then dislodged either digitally or with curved scissors, and the prostate is then "peeled off" the circular fibers of the bladder neck under direct vision. A hot laparotomy pad is then placed in the prostatic fossa and allowed to remain for several minutes while the bladder neck is trimmed and the two hemostatic sutures are placed at 5 and 7 o'clock. A V-shaped piece is removed from the floor of the bladder neck only when there is fibrosis or a median bar present. We have not done this as a routine measure and have yet to see our first postoperative stricture (it is two years since our first operation). Should the posterior lobe and capsule be torn away during the enucleation, no problem is encountered, as there are no large vessels in this area to contend with. The rectum can be seen coursing downward, and the seminal vesicles are accessible under the neck of the bladder. We have done one radical retropubic prostatectomy in which we removed the entire prostate, seminal vesicles and a cuff of the bladder neck. After the bladder neck has been treated, the lower portion of the interior of the bladder can be *inspected, and in most* instances the ureteral orifices can be seen. Even in patients with large glands which intrude well into the bladder, there has been no interference with these orifices. The hot pad in the prostatic fossa is then removed, and any open vessels can be seen and tied. We have not resorted to electrocoagulation. The urethral catheter is then passed, and the tip which emerges in the fossa is grasped and brought up into the wound. After the catheter eyes are cleared, the catheter is replaced in the prostatic bed with the tip well up in the bladder. In cases in which there is some oozing from the fossa of the gland, an inflated Foley catheter may be used for compression hemostasis. However, in 3 instances we have seen the inflated catheter slip down in the fossa with consequent emergence of the tip of the catheter out of the bladder. In these cases the tip became lodged under the neck of the bladder (fig. 3). To obviate this complication, one of us (F. P. T.) has devised a catheter which has a tip measuring 2½ inches (6 cm.) from the bag. The catheter is also wire reinforced to prevent the lumen from collapsing when the bag is fully inflated (fig. 4). Compression hemostasis by this method is maintained for several hours only, when the bag is deflated. One of us (F. A. B.) has suggested an open end catheter with a removable tip and eccentric bag which is placed in the bladder (fig. 5). The use of absorbable hemostatic agents around the bag when compression hemostasis is used and packed in the fossa when compression hemostasis is not used has been discontinued by us in our later cases, after the occurrence of calculi with gauze nucleus in 2 of our cases.

Good drainage by catheter is the most important single factor for the postoperative comfort of the patient. After the anterior capsule has been closed with interrupted sutures, the catheter is tested with a hand bulb syringe. Good, water-tight suturing of the capsule need not require layers of sutures. In many instances we have used only two or three interrupted stitches. In approximating the cut ends of the capsule after removing the largest gland, which weighed 173 Gm., we made only three sutures. When good irrigation is assured, the wound is closed in the usual manner with a drain in the prevesical space.

SELECTION OF CASES

In our first series of 23 retropubic prostatectomies,[4] 65 per cent of our subjects were cardiac patients with bundle branch block or auricular fibrillation, whose obstructing prostates weighed from 8 to 110 Gm. There was no selection of patients except for prostatic carcinoma, vesical diverticulum or tumor and the like. Since then the smallest prostate removed weighed 30 Gm. A study of the large veins in this area reveals the proximity of the trifurcation of the deep dorsal vein of the penis to the neck of the bladder when a small gland is present, which increases the hazard of bleeding. Large benign glands, which may or may not intrude into the bladder, are ideally removed by the retropubic method. We found no contraindication for this operation in obese patients. With proper retraction in an obese patient who has a large prostate, the operation can be completed without difficulty. Figure 6 shows such a patient three weeks after leaving the hospital, during which interim he had lost 15 pounds (7 Kg.).

POSTOPERATIVE COURSE

More than in many major operations, in this operation the comfort of the patient, in Millin's words, "must be seen to be appreciated."[5] This depends on the working condition of the catheter. When the catheter drains freely, one can almost be certain that the patient will have a comfortable postoperative course. Many of our patients received no morphine or meperidine hydrochloride after operation. Free drainage was used, and the bladder was irrigated every half-hour for the first two hours and every two hours thereafter for the first day. If the urine was not too bloody, the patient was allowed out of bed on the second or third day, provided, of course, that there was no medical contraindication. When the catheter is removed on the fifth or sixth day, the patient should be able to void. If he is unable to do so, the catheter should be reinserted, and an additional day or two of catheter drainage should correct this situation. Some British surgeons leave the catheter in for eight or nine days routinely. Our youngest patient, who was 47, voided around his catheter seventeen hours after operation; the catheter was removed, and the patient remained continent with good control thereafter. As a general rule it is easy to reinsert a catheter after the first

postoperative day, but some difficulty is met if it is tried within the first twenty-four hours. Because of this, we doubly check the drainage of the catheter while the patient is in the operating room and fix it in position. When a straight catheter is used, a suture is taken in the glans penis or in the prepuce to anchor it in position.

1. *Stress Incontinence.*—In several cases there was some stress incontinence, which responded immediately to muscular exercises, such as the patient's voluntarily starting and stopping the stream three or four times during each voiding. We have had no case of permanent urinary incontinence.

2. *Residual Urine.*—The amount of residual urine varied from 0 to 20 cc. in all cases except 1, in which a running suture was placed in the neck of the bladder. The patient had residual urine of 45 cc. when last seen in our postoperative clinic, four months after operation.

3. *Osteitis Pubis and Periosteitis Pubis.*—These have been unknown in our series.

4. *Epididymitis.*—None of our patients had preliminary vasectomies. Unilateral epididymitis developed in only 1.

5. *Potency.*—All our patients who were potent before operation retained their powers after operation except 1. This includes our oldest patient, who was 88 years of age and who stated that now "the act lasts so long it is tiring."

6. *Postoperative Urethra.*—The endoscopic picture of the posterior urethra is remarkable. The walls are clear and smooth as early as six weeks after operation. Even the floor of the prostatic fossa, which is left open at operation, is firm and smooth.

CONCLUSION

A series of 40 retropubic prostatectomies is presented, which have been done in various ways so that we could learn the most from each step. These were done in a city hospital where patients were admitted generally in an undernourished state and with acute urinary retention. A brief account of the distribution and configuration of the prostatic plexuses of veins, which is so important in retropubic surgery, is presented, and new instruments are introduced. We feel that retropubic prostatectomy, as a rule, should not be done on prostates which weigh less than 30 Gm. and that all large smooth elastic glands are easily and ideally treated by this method. Small prostates are not best removed by this method because of (1) the proximity of the large branches at the trifurcation of the deep dorsal vein of the penis when the gland is small, (2) the difficulty in enucleating small glands and (3) their amenability to treatment by transurethral surgery. It has been necessary for us to do one secondary operation for hemorrhage. The approach here was the same as in the first operation; the bleeders were tied, the fossa was not packed and the bladder was not opened. Another secondary operation was done because of a suprapubic sinus due to impingement of the tip of the catheter under the posterior lip of the bladder neck (fig. 3).

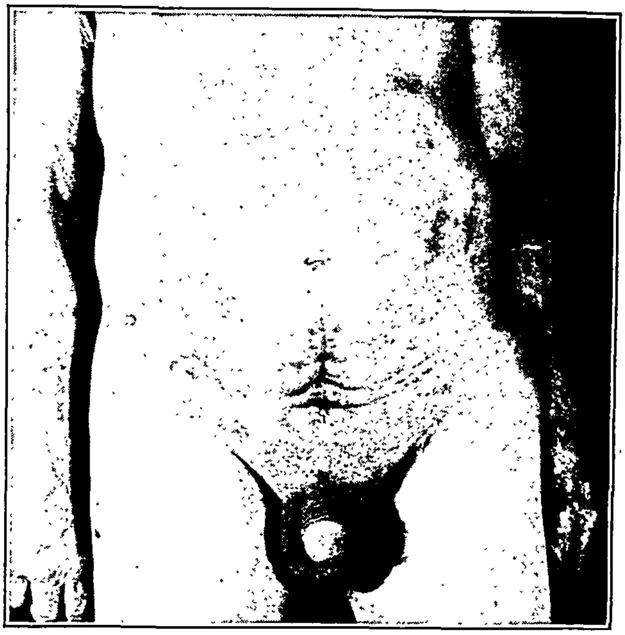

Fig. 6.—View of an obese patient thirty-one days after retropubic prostatectomy. He had lost 15 pounds (7 Kg.) since operation.

Penicillin and the sulfonamide drugs were not administered routinely in this series; yet we encountered no osteitis pubis. No preliminary vasectomy was done, and only 1 patient had postoperative epididymitis. Only 1 patient lost potency, and none was incontinent.

We are particularly impressed by the smooth convalescence of the patients and the satisfactory postoperative appearance of the posterior urethra and bladder neck seen on endoscopic examination. For these reasons, we feel that retropubic prostatectomies should be done in selected cases of large benign hyperplasias of the prostate in preference to other methods. The retropubic method is technically somewhat more difficult than the suprapubic, but its technic can easily be learned with moderate experience.

## ABSTRACT OF DISCUSSION

Dr. James Peters, Melbourne, Australia: After hearing the paper by Drs. Beneventi and Twinem I think that probably I shall spend a good deal of my time in America learning the technic of retropubic prostatectomy. This paper showed in extensive detail the ramifications of the prostatic plexus. I can really discuss here only one or two points—hemorrhage and stricture. I found hemorrhage at operation in my second case. When I got to the prostatic capsule I found that the diathermy machine was not working. Speed then became essential, and following the method which Dr. Beneventi has shown, the attack from the apex of the gland, I removed the prostate quickly and immediately replaced it with gauze. I was surprised at the conclusion to find that the loss of blood had been small, and I have followed that technic several times. I believe that the results are better, the quicker one can manage to get through a plexus, if it is controlled by suture—which is difficult—and diathermy, after clamps have been applied, then moving quickly through the capsule to enucleate the anterior portion of the gland and replace it by gauze, which I consider a very efficient hemostat. I feel that one method to avoid stricture is to cut out the V section posteriorly. In the 1 case of stricture that I have encountered, I cut laterally on either side and brought down a cuff of mucous membrane and sewed it to the prostatic bed. The long cuff of mucous membrane that comes up with the prostate is usually cut off, but it can be turned down and sewed to the base of the prostate, and I think that will obviate stricture. There is a shelf, which is very pronounced posteriorly at the vesicle neck, and I think that is one method of control of stricture. A method I use in fixing the catheter in the prostatic cavity is to put a suture through the tip and bring it out through the bladder and up through the abdominal wound, cutting it off in seven days, because that makes one certain that the tip of the catheter is held in position.

Dr. Grayson Carroll, St. Louis: Drs. Twinem and Beneventi gave a splendid description of the anatomy in the retropubic approach. The delineation of the blood vessels is especially helpful. Overcoming minor technical difficulties, better use of suction and recognition of anatomy have simplified the retropubic operation for my co-workers and me; we have become quite enthusiastic about it. We have had no deaths. We had 1 case of osteitis pubis.

Dr. Nels F. Ockerblad, Kansas City, Mo.: These experiences with the retropubic operation are illuminating. Drs. Twinem and Beneventi have mastered this operation and have found that it produces results comparable to the more usual procedures. They have pointed out also the pitfalls. The retropubic space, or the space of Retzius, is even today not to be approached lightly. Before going all out for retropubic prostatectomy, it would be well for one to see how patients subjected to that operation are managing after five years. My opinion is that it is not an operation to replace any of the present procedures, but that on occasions it may be an extremely valuable approach.

Dr. Francis P. Twinem, New York: We do not commend a retropubic operation for all types of prostatic disorders. We believe that all urologists should learn to perform this type of operation and feel sure that they will find it exceedingly useful in properly selected cases. As to osteitis pubis, we have had no case in our series. I think these cases of osteitis pubis are usually due to traumatic injury of the periosteum, probably by needle pricks or rough handling in the exposure of the anterior surface of the capsule. We have not performed vasectomies in the series we reported in this paper, and we have had no instances of epididymitis. I had 1 case of epididymitis in a retropubic operation which is is not included in this series—a private case. All cases of the series reported were in ward patients in Lincoln Hospital. In a private case I performed a vasectomy, following which there was epididymitis. I think the epididymitis was probably incubating at the time I tied off the vas deferens. We have had no instances of incontinence. The catheter which was demonstrated is the same type known as the Emmett catheter, except that in the region of the bag there is a spiral coil, the purpose of which is to prevent compression of the lumen when the bag is distended. I agree with the discussants who stated their belief that the bag should be distended in the prostatic bed routinely. It is often advisable to do this; however, where there is a fair amount of bleeding, the bag should not be allowed to remain distended for long—a few hours usually suffices. It should not be distended too fully in the first place. If these principles are followed I am sure distention of the bag will not give rise to incontinence in any case. The incision in the anterior surface of the capsule of the prostate may be made in a longitudinal direction as well as transversely. This should depend on the size of the prostate and the distribution of the blood vessels. In some cases the longitudinal incision will require the severing of fewer blood vessels than a transverse incision. As a general rule, however, we employ the transverse incision. There are so many methods of removing a prostate today that it leaves one a little confused. It may be that we are in what the Roman poet Horace described as "a time of delirium" in regard to this situation. However, following that period there was the Golden Age of Caesar Augustus. It may be that after all the indications for the various methods of prostatic operations are fully discussed and all the complications considered, we will arrive at the golden age of prostatic surgery.

# CUTANEOUS GRANULOMA FROM ACCIDENTAL CONTAMINATION WITH BERYLLIUM PHOSPHORS

A. D. NICHOL, M.D.
and
RAFAEL DOMINGUEZ, M.D.
Cleveland

During the past ten years an appreciation of the peculiar properties of beryllium led to its utilization in a variety of industrial processes and products.[1] Unfortunately, in occasional persons exposed to a beryllium-contaminated atmosphere an illness developed characterized by a distinctive clinical course and a generalized granular pattern seen on roentgen examination of the lungs.[2]

Despite the failure to produce generalized or pulmonary chronic granulomatosis[3] by exposure of experimental animals to beryllium compounds, clinical observations continue to emphasize the probable causative significance of zinc beryllium silicate in this disease.[4] Characteristic histologic changes and the presence of abnormal quantities of beryllium in the tissues and urine of such patients furnish further presumptive evidence incriminating these beryllium phosphors. Similar detailed observations in persons exposed to beryllium oxide and beryllium alloys[1a] tend to

single out beryllium as the principal known causative factor. Recent observations[5] that typical histologic changes follow the accidental introduction of beryllium phosphors in the skin provide additional and direct evidence of the toxic properties of beryllium. The increasing production and handling of fluorescent light bulbs, sign tubes, radio appliances and other articles of general distribution have multiplied the chances of accidental contamination of the skin and subcutaneous tissues with beryllium.

Essentially all fluorescent light bulbs manufactured in America, to the present, have contained a phosphor with varying quantities of zinc beryllium silicate (1.4 zinc, 0.6 beryllium), manganese and small amounts of finely dispersed mercury. The beryllium content of these phosphors has varied from approximately 2 to 15 per cent, expressed in terms of beryllium oxide. Since 1943 all manufacturers have used a low beryllium phosphor. In 2 of the cases of the only previous report[5] of granuloma of the skin resulting from accidental laceration by fluorescent light bulbs, the beryllium content of the phosphor was taken to be 2 per cent. In the cases of the present report the phosphor used never exceeded 4.0 per cent beryllium oxide, that is, less than 1.5 per cent, by weight, of beryllium. Previous experience has illustrated the relatively high incidence of chronic pulmonary granulomatosis following exposure[1a] to the high beryllium content phosphor, but the cutaneous granulomas following the accidental introduction of low beryllium phosphors seemingly prove that the beryllium content of the phosphor is of minor significance in the causation of these serious industrial diseases.

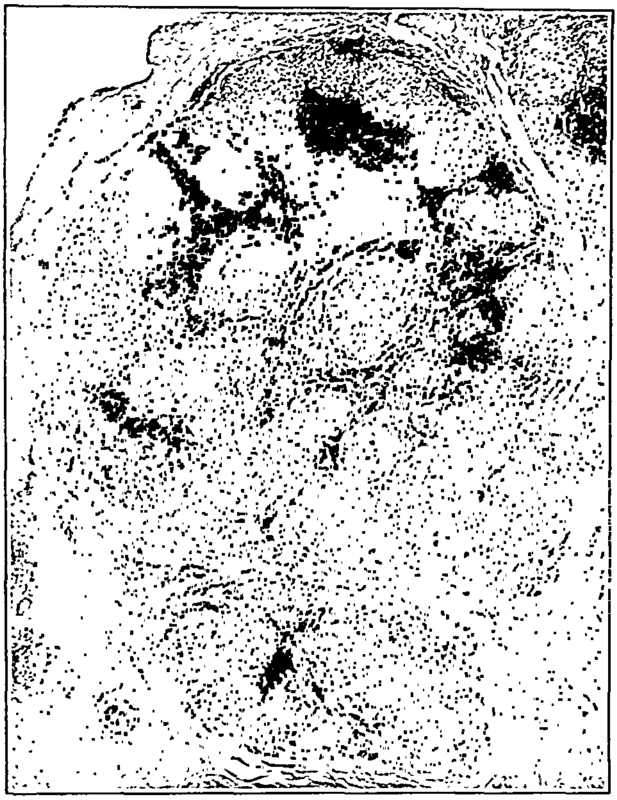

Fig. 1.—Discrete and conglomerate sarcoid bodies in fibroadipose tissue and in lymphoid tissue of suboccipital region (case 1). The majority of the granulomas show advanced hyalinization. (Hematoxylin and eosin stain, × 118).

In this paper the clinical, histologic and spectrographic data on 2 patients with indolent lesions of the skin following accidental lacerations with broken fluorescent light bulbs are presented.

## REPORT OF CASES

Case 1.—A white man, aged 36, was seen Dec. 9, 1945, with a chief complaint of exhaustion and shortness of breath on exertion, varying cyanosis, chronic cough, night sweats, diminished appetite and progressive weight loss of 20 pounds (9 Kg.). A recurring suppurative process of the skin in the suboccipital region had been present for the previous six years. The patient had been constantly exposed to beryllium phosphors during employment from August 1938 to March 1943. On June 6, 1939, the patient came in contact with a high voltage electric current and fell backward, crashing through a large crate of fluorescent lamps. He sustained extensive lacerations of the back of the head and neck and a slight compression fracture of the eighth dorsal vertebra. The lacerations were sutured and promptly healed. Subsequently a pronounced keloid formation occurred in the suboccipital region, and there was intermittent pain, swelling and tenderness in this area. Spontaneous local drainage was followed by the temporary subsidence of symptoms, but incrusted, slightly tender ulcerations persisted. These wounds had been explored on several occasions, and small foreign bodies, presumably glass, had been removed. The indolent process was an annoyance to the patient's family and to several attending physicians, but was almost disregarded by the patient. Several roentgenograms of the neck revealed small foreign bodies, presumably glass. Repeated roentgen examinations of the chest, the last one in April 1944, showed nothing of significance. In September 1945, the patient experienced shortness of breath on exertion, paroxysmal orthopnea and progressive loss of weight. During the physical examination in December, the patient was slightly dyspneic at rest, with slight cyanosis of the nail beds and moderate cyanosis of the lips, tongue and conjunctivas. A few rales were scattered throughout the lungs. There were scattered keloid formations in the suboccipital region, which were irregularly incrusted, reddened and tender. The red blood cell count was 7,800,000, hemoglobin 20.0 Gm. and the hematocrit 62 per cent. The vital capacity was 2.5 liters (expected normal 3.7 liters). The oxygen content of the arterial blood at rest was 21.5 volumes per cent and the oxygen capacity 28.0 volumes per cent.

Interest was centered on an extensive infiltrative process in the lungs, manifested on roentgen examination by fine granular nodulations throughout the pulmonary parenchyma. Numerous examinations and diagnostic procedures were done in an attempt to determine the cause of the pulmonary disability. The localized tissue change in the suboccipital region was disregarded except by a senior nurse, Miss E. A. Garvin, who suggested that if beryllium was responsible for the chronic pulmonary disease it might also be responsible for the chronic fibrosis and suppuration in the neck. The patient was advised to have a biopsy of the neck tissues. At operation, in December 1947, the tissues removed were grossly different from the usual keloid.

*Pathologic Examination.*—The specimen consisted of four pieces of subcutaneous tissue from the neck. The material was divided roughly in half. One part was reserved for spectrographic examination. Sections from the other part (fig. 1) showed a fibroadipose tissue containing large numbers of small granulomas, circular in contour and fairly well encapsulated. Some of these granulomas were in part hyalinized, and a few were completely hyalinized. The cellular granulomas consisted of monocytic elements similar to the epithelioid cells of the tubercle, but there was no caseation and there were no giant cells. A few of the granulomas, whether cellular or fibrous, were surrounded by lymphocytes. In one of the sections there were a few areas of lymphoid tissue studded with granulomas. These lymphoid aggregates might be remnants of lymph nodes.

but the absence of both follicles and sinuses and the peripheral fibrosis of the granulomas made the identification difficult. Moderate quantities of beryllium were present in the half of the specimen submitted for spectrographic analysis.

The original biopsy specimen had included most of the largest keloid, but it was decided to excise the area widely in order to circumvent embedded glass and the accompanying local beryllium phosphor implant. A second operation was done in January 1948.

The second specimen consisted of a flat, roughly rectangular piece of fibroadipose tissue measuring 5 by 5.5 cm. and about 0.4 cm. in thickness. Blocks for sections were taken from the midportion of each border. The remaining tissue was divided into two parts: one, from near the scar of the first operation, was labeled "scar"; the other was labeled "adjacent." Both parts were submitted separately for spectrographic analysis. The sections consisted of fibroadipose tissue with a slight perivascular round cell infiltration. Granulomas of the type already described were found in sections from the border near the site of the first operation. No granulomas were found in the sections from the other borders of the specimen.

Spectrographic analysis of the "scar" showed the presence of moderate quantities of beryllium, while the histologically normal, "adjacent" tissue contained no beryllium.

*Other Observations.*—At the time of the second operation the patient's general condition was slightly worse. Mild to moderate cyanosis was constantly present. Transient attacks of orthopnea and increased cyanosis sometimes occurred spontaneously and invariably followed more than slight effort. Cor pulmonale had definitely developed, and the patient had recently experienced a mild, transient attack of pulmonary edema. The physical examination showed no gross change except for continuing weight loss. The blood pressure was 116 systolic and 86 diastolic, and the heart rate was 112. The second heart sound was accentuated in the pulmonic region, and a gallop rhythm was occasionally present. The urine had a specific gravity of 1.025, with albumin 0 and sugar 0. Microscopic examinations showed 6 to 8 white blood cells and occasional hyaline casts per high power field. The red blood cell count was 7,520,000, white blood cell count 7,100 and hemoglobin 18.7 Gm. The hematocrit was 56 per cent. The differential count showed 63 per cent segmented forms, 28 per cent lymphocytes, 8 per cent monocytes and 1 per cent stab forms. The serum protein was 7.4 Gm. and serum albumin 2.0 Gm. per hundred cubic centimeters. The carbon dioxide content of venous blood was 48 volumes per cent. The nonprotein nitrogen was 38 mg. and the blood sugar 90 mg. per hundred cubic centimeters. The sulfobromophthalein test of hepatic function showed 5 per cent retention after 45 minutes. There was a decided right axis deviation in the electrocardiogram with sharply peaked T waves in leads 2 and 3. Roentgenograms showed little change in the generalized granular pulmonary nodulations except for an increased confluence of the shadows in the middle third of the lung fields. The transverse cardiac diameter had increased from 14.0 to 14.7 cm., and the pulmonary artery was definitely more prominent.

The patient spent the remainder of the winter of 1948 in New Mexico, without beneficial effect on his general debility and with no improvement in his respiratory difficulties. It is of interest that extreme exhaustion and moderate dyspnea occurred at rest while the patient was crossing the Raton Pass, altitude 6,638 feet, on his return home in May 1948. In June 1948 he had a short period of chest pain, severe orthopnea, increased nonproductive cough, moderate nausea and fever. The blood pressure dropped to 76 systolic and 56 diastolic, but there was no evidence of congestive cardiac failure. Roentgen examination showed a confluent shadow in the right upper lung field suggestive of early pneumonia. Penicillin was immediately administered, and twelve hours later the patient's temperature was normal. The white blood cells decreased from 23,400 to 11,400; the extreme dyspnea lessened, and the patient was distinctly improved. At the operative site in the suboccipital region there was a thin scar. Multiple punctate incrusted lesions were still present, scattered throughout the occipital region, and they continued to exhibit evidences of indolent ulceration. These small lesions had been recognized at operation, but their removal was not considered feasible. In June 1948 the urine contained 0.0007 micrograms of beryllium per 50 cc. sample. At the time of last examination the removal of the beryllium-containing tissues had resulted in local healing, but there had been no improvement in the general physical disability or the pulmonary granulomatosis. It was the consensus of all observers that the patient was slowly deteriorating.

Case 2.—A white married woman, aged 46 years, was admitted to St. Luke's Hospital on May 19, 1948, complaining of dyspnea on exertion, cough, increased sweating, diminished appetite and weight loss of 24 pounds (11 Kg.). The patient was born on a farm and spent her youth there doing extremely hard work. She was married at 18 years. In 1921, when 19 years of age, she had an emergency appendectomy for acute appendicitis. Her fourth pregnancy, in 1927, was complicated by prolonged fever. An abscess of the left kidney was drained in the fourth postpartum month. After the sixth pregnancy, in December 1930, the patient had an acute illness, with fever, transient coma and grossly bloody urine. Good health was regained after lavage of the renal pelves. Her seventh and eighth (last) pregnancies were normal.

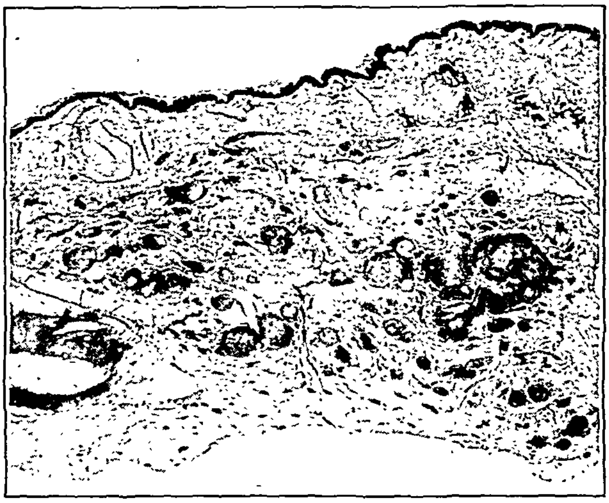

Fig. 2.—Low power view of a section from slice B of the scar in the forearm (case 2) showing the large number of sarcoid bodies in dense fibrous tissue. (For the size and number of sarcoids in this section, see text and table 1.) (Hematoxylin and eosin stain, × 6.9.)

Her work record included housekeeping duties with two short periods of employment in a dress manufacturing establishment. There had been no known exposure to industrial toxic hazards. When she was employed in a beryllium industry, in February 1942, she considered herself in good health and able to work hard. Her weight at this time was 175 pounds (79 Kg.), and her blood pressure was 188 systolic and 100 diastolic. She had no symptoms suggestive of vascular or myocardial disease, but arterial hypertension was consistently present and treated by various medicaments. A routine roentgenogram of the chest (14 by 17 film) in September 1947 was essentially normal.

Her present illness began about October 1947. The initial dyspnea on exertion and nonproductive cough were attributed to an acute infection of the upper part of the respiratory tract. A similar diagnosis was made in January 1948, during a temporary exacerbation of the aforementioned symptoms with associated fever. She was able to walk slowly without distress, but her exercise tolerance gradually decreased, and a short fast walk or climbing one flight of stairs caused moderate exhaustion, dyspnea and paroxysms of coughing. She had used lipstick for several months in order to conceal blueness of the lips. Despite these difficulties the patient did not consider herself incapacitated. Medical interest in her condition was stimulated by generalized granular shadows throughout the lung fields seen in a routine roentgenogram of the chest taken on April 30.

In the subsequent examination, a history was secured that the right forearm was severely lacerated by a broken fluorescent light bulb in August 1946. The wound was sutured and healed promptly. In January 1948 there was swelling, pain and tenderness about this scar. No foreign bodies were demonstrated in roentgen examination. The scar became hypertrophic, reddened, painful and tender. The symptoms were relieved after self-induced drainage of an indurated area. Recurrence of local signs and symptoms were intermittently present and relieved by spontaneous drainage. There was no pain about the scar on the patient's admission to the hospital. The respiratory rate and temperature were normal. There was slight blueness of the lips and nail beds, but no clubbing of the fingers and toes. The blood pressure was 210 systolic and 138 diastolic. Minimal evidence of arterial disease was present in the retinal arteries, and there was slight distention of the retinal veins. The heart sounds were normal, and the rhythm was regular. The lungs showed no abnormalities. There were two surgical scars of the abdominal wall and one surgical scar in the left lumbar region. Lax abdominal walls and diffuse abdominal tenderness were present without other abnormalities. Breath holding varied from 28 to 33 seconds. The vital capacity was 1.6 liters (expected normal 3.4 liters). The reaction to an intradermal tuberculin test, 1 : 10,000, was negative. The urine was normal except for a beryllium content of 0.001 micrograms per 50 cc. sample. The red blood cell count was 6,280,000, hemoglobin 16.9 Gm. and white blood cell count 6,000. The differential count showed 61 per cent segmented forms, 36 per cent lymphocytes and 3 per cent monocytes. The corrected sedimentation rate was 19 mm. per hour. The reaction of the blood to the Kline test was negative. The blood nonprotein nitrogen was 36 mg. and blood sugar 104 mg. per hundred cubic centimeters. Smear of the sputum was negative for tubercle bacilli. The urea clearance test in three consecutive hours was 130, 133 and 115 per cent of normal. The specific gravity of the urine varied from 1.018 to 1.024. The serum protein was 6.9 Gm. and the serum albumin 3.2 Gm. per hundred cubic centimeters. The sulfobromophthalein test of hepatic function showed retention of 8.5 per cent in 45 minutes. The result of the cephalin flocculation test was normal. The electrocardiogram showed a left axis deviation, a normal sinus rhythm, with a rate of 94, and a P-R interval of 0.14 seconds. Roentgen examination of the chest revealed fine granular stippling throughout the lung fields. There was calcification of the right bronchopulmonary lymph nodes and an area of calcific density in the right lower lung field. The heart was normal in size and configuration.

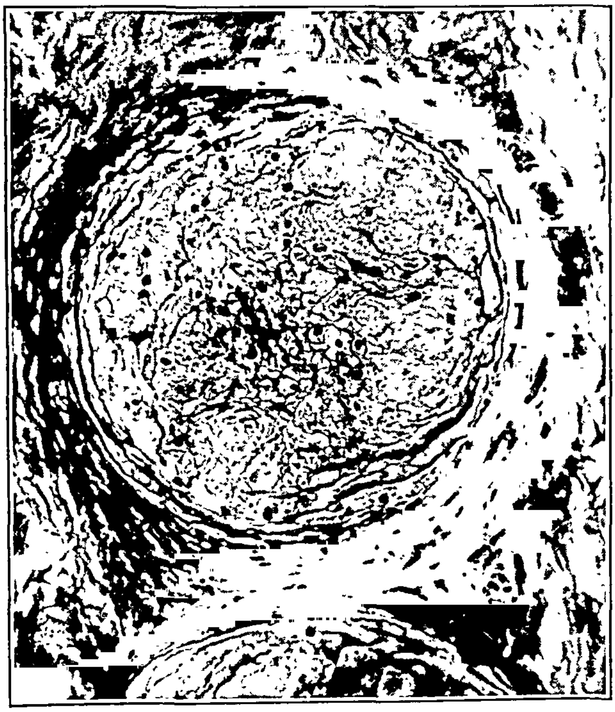

Fig. 3.—Photomicrograph of simple sarcoid in the scar of the forearm (case 2). Azocarmine stain. Tri X plate, and green filter. This figure and figures 4 and 5 show the dense peripheral fibrosis of the sarcoid and the progressive fibrosis and hyalinization of the central part (X 260).

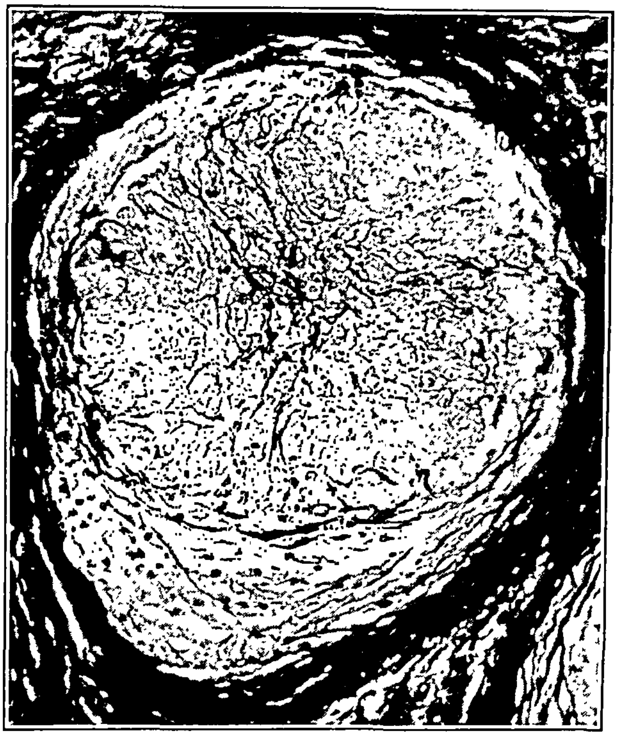

Fig. 4.—Photomicrograph of simple sarcoid in the scar of the forearm (case 2) (X 260).

Table 1.—*Sarcoid Bodies in Case 2*

| Slice | Area of Section, Sq. Cm. | Number of Sarcoid Bodies in Section | Number of Sarcoid Bodies per Sq. Cm. of Section |
|---|---|---|---|
| B | 4.215 | 118 | 28.0 |
| D | 5.743 | 210 | 36.6 |
| F | 3.052 | 120 | 39.3 |
| H | 2.313 | 78 | 33.7 |
| J | 2.335 | 37 | 15.8 |
| L | 1.323 | 6 | 4.5 |

The scar tissue of the skin over the right elbow was widely excised in May 1948. A small piece of skin, representing a recent scar of the right leg, was removed for control purposes.

*Pathologic Examination.*—The specimen consisted of (1) a scar from the right arm and (2) a scar from the right shin. The scar from the right arm was crescent shaped and measured 5 by 3 cm. and 1 cm. in thickness. The specimen was divided in consecutive slices labeled from A to L. The slices A, C, E, G, I and K were used for spectrographic analysis. Slices B, D, F, J, H and L were fixed in Bouin's fluid for microscopic sections. The specimen from the right shin was a flattened piece of skin with an oval contour, 1.2 cm. in length, 0.8 cm. in width and 0.5 cm. in thickness. On the skin surface of this piece there was an elongated depressed abrasion. The piece was sectioned along the abrasion. Half the material was used for spectrographic analysis. The other half was fixed in Bouin's solution, embedded in paraffin and sectioned.

All the sections from the scar of the right arm showed granulomas of sarcoid type (fig. 2). These bodies were either simple or conglomerate and varied considerably in size and number. The large ones were surrounded by dense collagenous fibers arranged in concentric layers. In many of the large sarcoids there were central pale areas consisting of coarse hyaline fibers, giving an appearance different from that of caseous tuberculosis (figs. 3, 4 and 5). The main cellular elements of the sarcoids resembled the epithelioid cells of tubercles. Besides these cells there were lymphocytes, especially in the periphery of the smaller sarcoids, and multinucleated giant cells of Langhans type (fig. 6). In the small sarcoids the contour of the cells could be outlined with ease. In the larger sarcoids the individual cells tended to form a syncytium and the cell bodies were difficult to outline. Toward the periphery of the sarcoids there were spindle cells with polar fibers oriented along the circumference. In some of the sarcoids there were angular slits containing small crystals. In one giant cell a dense club-shaped foreign body was present. No asteroid bodies were seen in any of the giant cells. With the azocarmine stain, practically all the sarcoids showed stainable fibers. These fibers were few in the smaller sarcoids, but became abundant in the larger sarcoids. The central pale areas mentioned before could be shown, by means of this stain, to consist of large numbers of collagenous fibers with few nuclei between. In slice D several sarcoids showed almost total fibrosis (fig. 5). In slice H a few conglomerate sarcoids lay immediately in contact with the epidermis. In this area there was flattening of the interpapillary pegs, reduction in the amount of melanin and of keratohyaline granules and a light staining of the malpighian layer. There was, however, no hyperkeratosis, no acanthosis and no ulceration. The number of sarcoid bodies in the slices are shown in table 1. The areas of the sections were then measured by projection and weighing. The number of sarcoids per square centimeter of section was then calculated with the results shown in table 1. The largest conglomerate sarcoid was found in slice D, 2.53 by 1.86 mm. The second largest was found in slice F, 1.68 by 0.93 mm. and the third largest in slice B, 1.53 by 0.86 mm. The largest number of large sarcoids was found in slice F. Of the simple circular sarcoids the largest, 0.86 mm., was found in slice B. The scar from the shin showed no granulomatous inflammation and no sarcoids.

TABLE 2.—*Results of Analysis of Tissue (Case 2)*

| Slice | Weight, Mg. | Beryllium, Micrograms | Beryllium Concentration, Micrograms/Gm. of Tissue |
|---|---|---|---|
| A | 193 | 0.005 | $25.9 \times 10^{-3}$ |
| C | 971 | 0.077 | $79.4 \times 10^{-3}$ |
| E | 224 | 0.013 | $58.1 \times 10^{-3}$ |
| G | 337 | 0.011 | $32.7 \times 10^{-3}$ |
| I | 241 | 0.003 | $12.4 \times 10^{-3}$ |
| K | 142 | 0.0003 | $2.1 \times 10^{-3}$ |

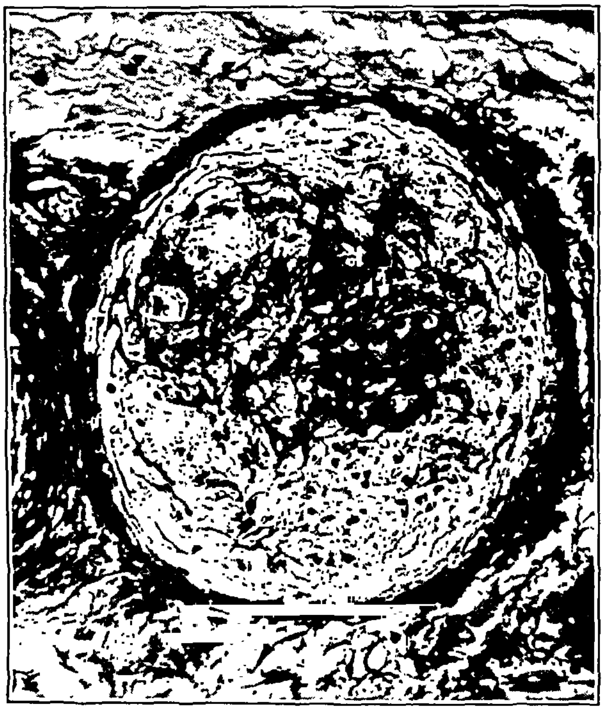

Fig. 5 (case 2).—Photomicrograph of simple sarcoid in the scar of the forearm (× 260).

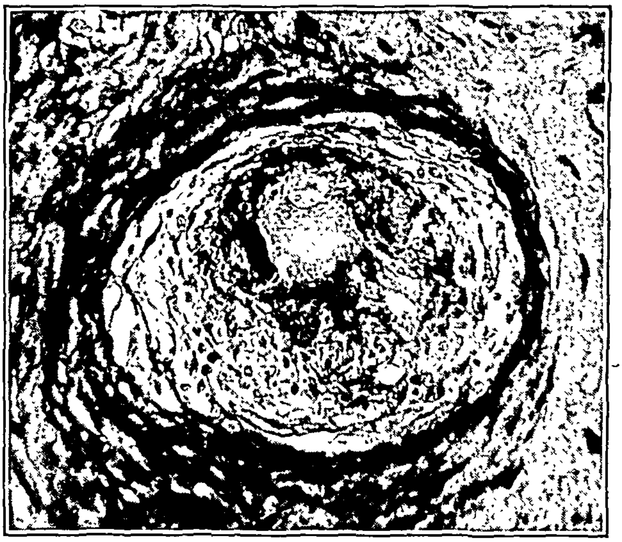

Fig. 6.—Photomicrograph of simple sarcoid in the scar of the forearm (case 2). Azocarmine stain. Tri X plate. Multinucleated giant cell surrounded by dense and hyalinized collagenous fibers (× 260).

The results of the spectrographic analysis of the tissue from the forearm is shown in table 2. There was no beryllium found in the skin from the right leg.

A report on this patient in September 1948 stated that her general condition was slightly improved, but there had been a small local recurrence of subcutaneous induration near the original scar on the right forearm.

## COMMENT

It is of interest that a peculiar granulomatous cutaneous lesion has now been reported as occurring in 5 patients who have had a zinc beryllium silicate compound accidentally introduced in and under the skin by lacerations sustained with fluorescent light bulbs. The histologic changes in the cutaneous lesions in our cases have been compared with postmortem material from chronic beryllium granuloma of lung which was furnished us by Dr. A. W. Vorwald of Trudeau Laboratories and Dr. F. R. Dutra of Kettering Laboratories. It has been the consensus of all observers that the histologic features of these lesions are similar.

We believe that the generalized granulomatous disease in our patients was caused by the beryllium-contaminated air to which they had been exposed for four and a half and six years, respectively. The surgical removal of the major beryllium deposits in the skin and subcutaneous tissues had no demonstrable effect on the pulmonary lesions. Three of the patients previously reported with local ulceration of the skin did not have the pulmonary form of the disease, and we have knowledge of 2 additional similar patients. Generalized pulmonary granulomatosis has not been reported to follow the accidental introduction of beryllium into the skin or subcutaneous tissues.

Significant quantities of beryllium have been found by spectrographic methods in the cutaneous tissues of our patients while control determinations of apparently uninvolved tissues in these patients have shown no beryllium. The rough parallelism between the quantity of beryllium present and the degree of sarcoid-like change in the tissues may be fortuitous. However, the count was not made on serial sections, and besides there is no way to estimate the size of the sarcoid bodies when these lesions are conglomerate. The observation that beryllium may persist locally in the tissues for a period of eight and a half years despite repeated ulceration and suppuration and despite possible removal by lymphatic channels (case 1) provides a further significant common feature between local beryllium disease in the skin and chronic beryllium granulomatous change in the lungs. Although chronic pulmonary granulomatous disease has not been produced experimentally, we believe that the study of these instances of cutaneous involvement lends additional support to the clinical evidence that beryllium is at least a major factor in the causation of a sarcoid-like disease which may cause extensive granulomatous change in several structures of the body.

Irrespective of the absolute etiologic basis for the chronic granulomatous change, it seems obvious that local lacerations caused by fluorescent bulbs coated with zinc beryllium silicate should be widely excised before surgical closure. Cure of the local lesion can be accomplished only if all contaminated tissue is removed.

### CONCLUSIONS

1. Chronic persistent granulomatous inflammation of the skin with ulceration may follow accidental lacerations by the present type of fluorescent light bulbs (glass coated with zinc beryllium silicate).
2. The histologic appearance of these skin granulomas is similar to that found in the lung in fatal cases of pulmonary granulomatosis occurring in beryllium workers.
3. Prevention of the cutaneous lesions can be accomplished only by wide excision preceding initial closure.

---

**The Number of Rats in Baltimore.**—A method of estimating populations of brown rats (Rattus norvegicus) by means of signs permits an estimate of the number of rats in Baltimore, Md. In September, 1947, the number of rats in a random sample of 359 blocks in the residential part of the city was estimated and the number of rats in the city calculated on the basis of rats per dwelling unit. This computation gives 139,855 rats, with a range (± 2 × standard error) of 119,000 to 158,000. On the basis of other sources of information an estimate of 26,000 rats in the commercial areas was made. A map of rat population according to census tracts agrees closely with the distribution of buildings in need of major repairs.—David E. Davis and W. T. Fales, The Distribution of Rats in Baltimore, Maryland, *The American Journal of Hygiene,* May 1949.

# DERMATITIS VENENATA FROM ORGANOMERCURIAL COMPOUNDS

## With a Comparison of Their Pharmacologic Action on Normal and Injured Skin

L. EDWARD GAUL, M.D.
and
G. B. UNDERWOOD, M.D.
Evansville, Ind.

In 1944, a report[1] was submitted on overtreatment dermatitis, which recommended that tinctures, salves and lotions containing a mercury compound should bear a "warning" on the label of the presence of a sensitizer. This article pointed out that a concise chemical and pharmacologic evaluation of drugs used on the skin might lead to a decline of the incidence of overtreatment dermatitis. A report[2] submitted in 1945, on overtreatment dermatitis of the feet, urged the Council on Pharmacy and Chemistry to "clean house" in the field of cutaneous drugs as it did with orally and parenterally administered drugs; tear apart the topical concoctions and define each cutaneous chemical in terms of dosage, indications and contraindications, and declare each therapeutic agent according to its chemical and pharmacologic properties. Again, it was recommended that all mercurials should carry a "warning" on the label of the presence of a sensitizer. Another report,[3] on overtreatment dermatitis in dermatitis venenata due to plants, stated, "The chemist and bacteriologist have supplied reams of data on the test tube performances of the myriads of antiseptics, but their toxicity—their incubation period on normal and abnormal skin—has been overlooked, often wrongly interpreted as infection. As a result, all the mercurial antiseptics at least need reconsideration."

On Jan. 3, 1948, the Council set forth that the field of usefulness of organic mercurials should be explored, proved and defined.[4] Evidently, the most important part of this challenge was the pharmacologic actions of the organomercurials on the skin, because it is this organ of the body that bears the brunt of the usefulness of these antiseptics. Accompanying the Council's statement was a report[5] on the bacteriostatic and bactericidal actions of some mercurial compounds on hemolytic streptococci. A surprising revelation was the bacteriostasis of hemolytic streptococci by these chemicals instead of their being bactericidal.

The lack of interest in cutaneous pharmacology was demonstrated by the fact that the authors[5] took up five pages in THE JOURNAL discussing bacteriologic data, but the actions of the mercurials on the skin were dismissed in two sentences. Reams of bacteriologic experiments do not prevent dermatitis venenata. Aroused by the challenge of the Council, Brewer[6] and Powell[7] presented bacteriologic observations which took up another five and one-half pages in THE JOURNAL. Their experiments defended the usefulness of mercurial antiseptics. These authors did not even mention the skin and declined to discuss the numerous reports on sensitization dermatitis from organomercurial compounds. Scientific argumentation, too, does not prevent dermatitis venenata. Interestingly, the color, red, really signifies danger.

Physicians reading these reports and counter reports would be left with the impression that the mercurial antiseptics were completely safe for use on the skin. Preventing and treating cutaneous infections is the reason for the popularity of these compounds. Advertisements,[8] a forceful educational channel, inform the public that "'it is dangerous to neglect wounds, however small; even scratches and small cuts may cause serious infection if they are not properly treated,' 'a first aid care for all minor wounds,' 'can be applied safely to small wounds.'" Patients and especially parents are disturbed by patch test reactions from their favorite household antiseptic. To them it seems preposterous that anything as important as an antiseptic would cause their skin to break out. There is no "warning" on these little bottles of red medicine. Advertisements inform physicians that organomercurials "inhibit and destroy organisms as they are released from sebaceous and sweat glands during the surgical procedure." (No proof is cited that cutaneous glands harbor organisms that are pathogenic.) Such statements leave an impression that the skin is a bacteriologic menace to the body. Failure to mention any toxicity boldly implies that the antiseptic is nontoxic. Physicians abhor producing in their patients dermatitis venenata from antiseptics. Where is the "warning" in this advertising that these compounds are powerful sensitizers?

### PHARMACOLOGIC ACTION OF ORGANOMERCURIALS ON NORMAL SKIN

The organomercurials are preferred for the preoperative preparation of the skin. The incidence of irritation has remained low enough to prevent limitation of their use in this field. No doubt, some cases of wound disruption, wound infection, stitch abscesses and delayed healing are unrecognized organomercurial dermatitis (fig. 1). The signs of the latter are indistinguishable from alleged secondary infections. The continued popularity of the organomercurials among surgeons is explainable on the basis that for the most part they are applied to essentially normal skin. Cutaneous chemicals outside the protective barriers of the skin (the *p*H, lipid coating, horny mantle) are pharmacologically in a different category than when they contact living skin. A normal skin, its protective barriers intact, can withstand repeated applications with mercurial antiseptics before it succumbs to sensitization dermatitis. To illustrate the importance of these barriers, patch tests with three to six different mercurial antiseptics were made postoperatively in 82 cases. The patients had been exposed to merthiolate® (sodium ethylmercurithiosalicylate) at least once and some of them two or three times. They never had had any skin trouble, and the surgical incisions had healed promptly. Not a single positive reaction to a patch test was recorded.[3] A conclusion that will find few dissenters is to the effect that mercurials on normal skin are unlikely to induce dermatitis venenata. This conclusion, of course, implies that the skin has not been previously sensitized to them. The present concept of the cutaneous pharmacologic aspects of the organomercurials obviously has been taken from the actions on normal skin.

### PHARMACOLOGIC ACTION OF ORGANOMERCURIALS ON INJURED SKIN

Disruption of the cutaneous protective barriers is the first prerequisite for these chemicals to induce acquired sensitization. The basic action of these antiseptics on injured skin was obtained by a review of current reports [10] on 20 cases. Eleven different authors observed similar actions.

1. *Organomercurials Applied for Antisepsis.*—Of the 20 cases, merthiolate® was causative in 14, mercurochrome® (disodium salt of 2, 7-dibrom-4-hydroxymercurifluorescein, merbromin, N.F.) in 3 and metaphen® (anhydride of 4-nitro-3 hydroxymercuriorthocresol, nitromersol, N.F.) in 3. Merthiolate® had the highest exposure ratio; thus it produces the greatest incidence of dermatitis.

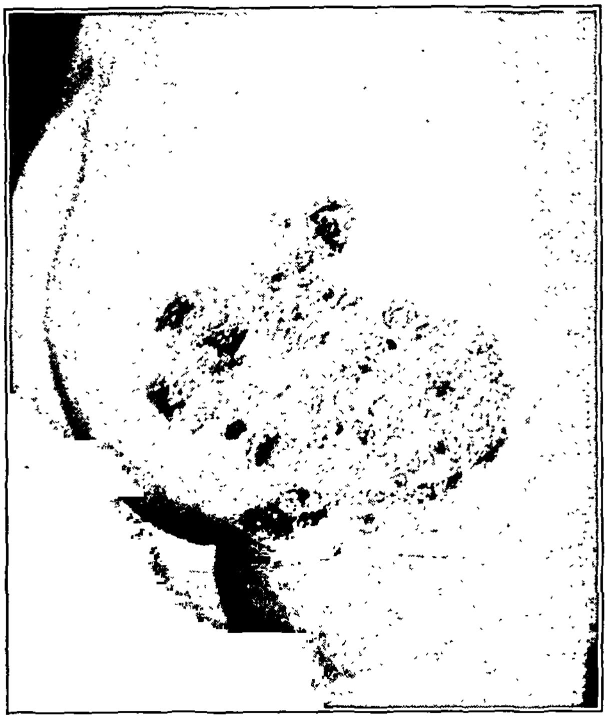

Fig. 1.—Wound disruption and ecthymatous dermatitis from merthiolate® (C. G., a 36 year old white woman). Merthiolate® was used to prepare the skin for a cesarean section in 1942 and for a second cesarean in 1944. The incision healed slowly with numerous pustules along the margin, and five stitch abscesses developed. In 1945, a nevus was excised from the right buttocks. The skin was prepared with *merthiolate.®* Healing progressed satisfactorily for one week; then the incision opened. Merthiolate® was applied to the gaping wound and surrounding skin. Within a few days the wound drained profusely, and the entire area of skin painted with the preparation became a deep-seated pustular dermatitis. It took six weeks for the wound and the dermatitis to heal.

2. *Cases*—Age, sex or color were not factors in the production of dermatitis by mercurial antiseptics. Our series of cases showed a proportionate incidence among Negroes. No personal or familial predisposition was encountered. The organomercurials then are classed as chemicals, readily inducing acquired sensitization dermatitis.

3. *Type of Cutaneous Injury.*—The kind and degree of trauma were relatively unimportant. the crucial factor being disruption of the protective barriers of the skin. The types of cutaneous injury most commonly encountered were trauma due to physical agents, burns and so on; mechanical agents, abrasions, lacerations, scratches and surgery; chemical agents, dermatitis venenata from any cause, and infections. A specific infection, like chickenpox, disrupts the skin barriers, and the likelihood of a superimposed dermatitis from application of a mercurial is as great as from application of an antiseptic to an incised wound. In a cutaneous infection which has become severer or has spread, an inquiry into the antiseptics that have been applied might reveal the cause. The onset of dermatitis following an injury to the skin is an everyday occurrence. Checking the chemical applied may reveal the cause without necessitating long discussions about the rarity of the morphologic changes. Antiseptics and germicides surpass all other topical chemicals in producing overtreatment dermatitis.[11] Figure 2 illustrates a typical case.

4. *Location.*—The areas of skin most subject to trivial trauma or alleged fungus infections of the feet, with or without "ids" on the hands, are the commonest sites for primary sensitization dermatitis from mercurial antiseptics. An illustrative case is shown in figure 3.

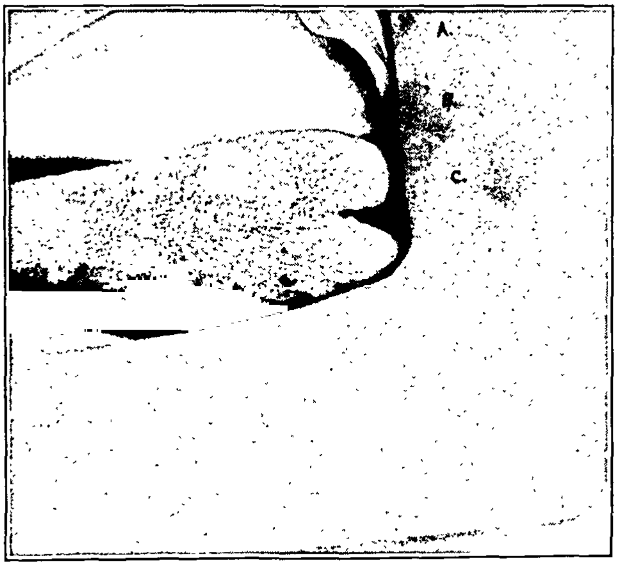

Fig. 2.—Dermatitis due to merthiolate® of three weeks' duration in N. D., a 16 year old white school girl. The dorsal lateral surface of the right hand was scratched, and *merthiolate® was applied to the injured* area to prevent infection. In a few days, an eruption appeared which a physician considered to be a secondary infection, and the area was again painted with merthiolate.® The eruption promptly spread. Positive reactions to patch tests are shown on the left arm to (*A*) aqueous merthiolate® (*B*) mercuric chloride and (*C*) *tincture of merthiolate.®*

5. *Sources of First Application.*—Thirteen patients were exposed by physicians or personnel supervised by them. This is proof that physicians have not been informed about the sensitizing potentialities of these compounds. Seven patients were exposed by self application—proof of the effectiveness of lay educational programs on what to do for minor traumas.

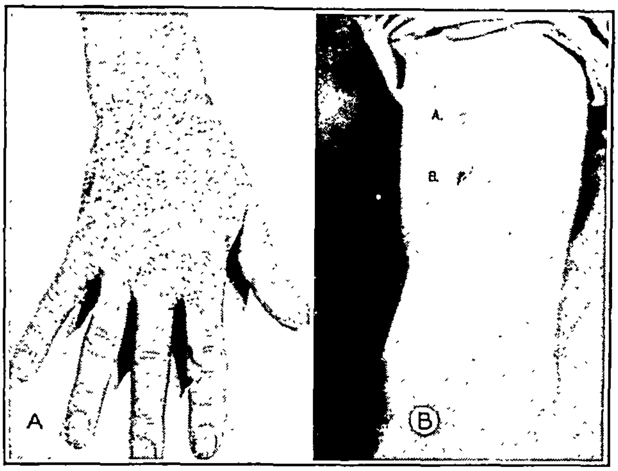

Fig. 3.—*A*, right hand of W. T., a white male meat cutter, aged 46. For six years, he had had a recurrent vesicular eczematization of the dorsal aspect of the hand. There had been remissions for as long as one year. In January 1946 an acute recurrence developed. The reaction to a patch test with mercresin,® the antiseptic used in the first aid room at his place of employment, was negative. It was then ascertained that six years previously merthiolate® had been in use in the first aid room and this antiseptic had been applied to a laceration on the right index *finger. The cause of the recurrence was traced to the antiseptic used in* the home, merthiolate.® Reactions to patch tests with ammoniated mercury 5 per cent, metaphen,® and mercuric chloride 5 per cent were negative. Reaction to patch tests with tincture and aqueous merthiolate® were positive (fig. 3*B*). This case is an example of the remarkable specificity of the organomercurial sensitizations. *B*, Positive patch test reactions to (*A*) tincture merthiolate® and (*B*) aqueous merthiolate.®

6. *Duration of Applications.*—This is the second prerequisite for mercurial dermatitis. The time interval in the 20 cases varied from one day to several weeks. For a given injury, as the duration of applications increased, the likelihood of sensitization increases proportionately. The organomercurials are sufficiently potent sensitizers so that, with the first and second prerequisites met, dermatitis can be produced in almost anyone.

7. *Incubation Period.*—The seemingly unpredictable periods of exposures before onset of sensitization introduces the third prerequisite; the chemical structure of the compound applied. The formula of the organomercurials classes them as typical sensitizers. Once they have produced cutaneous sensitization, reactions to patch tests are prone to occur in progressively higher dilutions. Reactions have occurred to dilutions of 1 : 1,000,000. Ellis[101] commented on the possible dangers from injection of serums and plasmas containing merthiolate.® These dangers are more real than generally believed. One brand of allergens for intradermal tests contains merthiolate.® A high dilution of an organomercurial in a skin remedy does not lessen the likelihood of a sensitization dermatitis. A patient who requires five days or more for dermatitis to appear is doubtless being sensitized to the particular antiseptic. A patient who requires two to five days is probably being sensitized, but these short reaction periods also suggest a possible preexisting, subthreshold sensitization. Patients in whom dermatitis develops in less than twenty-four or forty-eight hours have been previously sensitized.

---

11. Gaul.[1] Underwood, Gaul, Collins and Mosby.[2] Underwood and Gaul.[3]

*8. Signs of Dermatitis.*—A common observation has been the gradual development of inflammation in an injury following the application of a mercurial. Perhaps a better designation would be delayed healing. Reapplying mercurials at the site of these signs apparently speeds up the sensitization process. The appearance of pustules in or around the wound is a cardinal sign of sensitization, and a positive reaction to a patch test is probable. Another equally common observation is that the initial injury practically heals and then suddenly disrupts with profuse drainage. Around the injury a vesicular eczematization appears, which may rapidly spread. Application of a mercurial to this reaction frequently produces generalized dermatitis.

A. Primary Sensitization Signs at Site of Injury: Eczematization which may be dry, fissured, papular, vesicular, pustular, bullous or hemorrhagic is the classic sign of dermatitis due to antiseptics. While the signs are characteristically nonspecific, the sensitizing chemical is highly specific; that is, a simple chemical like merthiolate,® in sensitizing the skin, produces a remarkable variability in the morphologic aspects of the eruption. A pustular eruption is common, which explains why the disease in these patients is incorrectly diagnosed as infection, secondary infection, infectious eczematoid dermatitis or fungus infection. A diagnosis of fungus infection has become so popular among laymen that the diagnosis "eczema" is becoming obsolete. Physicians, too, seldom use this term. A diagnosis of an "infection" has tended to replace the term "eczema." The latter suggests zinc oxide ointment for treatment, but infection suggests an antiseptic, in the wake of which has arisen the specter of overtreatment dermatitis. Howell,[12], too, pointed out that sensitization dermatitis from topical medicaments following the treatment of some trivial eruption, as pruritus, miliaria, a superficial burn, an insect bite, poison ivy, sunburn or athlete's foot, is a common and everyday occurrence. When contact dermatitis occurs during the course of topical chemotherapy, the common mistaken interpretation is that infection, such as erysipelas or cellulitis has occurred or that the patient has contracted poison ivy dermatitis.

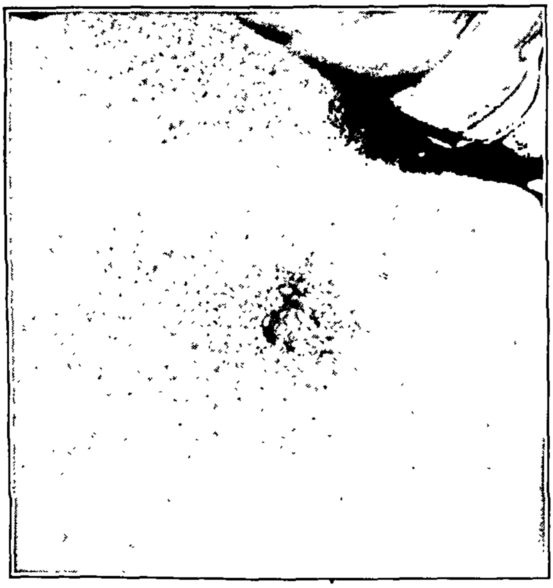

Fig. 4.—J. G., a 54 year old white man, sustained a burn on the left leg. This was painted with merthiolate®; in about ten days the wound was almost healed. Overnight, vesicular eczematization developed in the burned area. Merthiolate® was applied to this eruption, and within three days a generalized vesicular dermatitis appeared. One year later, the right thumb was lacerated and merthiolate® was applied to prevent infection. Within twenty-four hours the thumb became the site of a pustular eczematization, and four days later, lymphangitis with adenopathy developed associated with fever and leukocytosis. After the thumb had healed,, a patch test with tincture of merthiolate® on the right arm produced a bullous reaction in less than twelve hours. The reaction to a patch test with tincture of merthiolate® is shown on the left arm sixteen months later. There was no diminution in the intensity of the reaction to the patch test. From all available evidence, the duration of organomercurial sensitization may be months, years or even a lifetime.

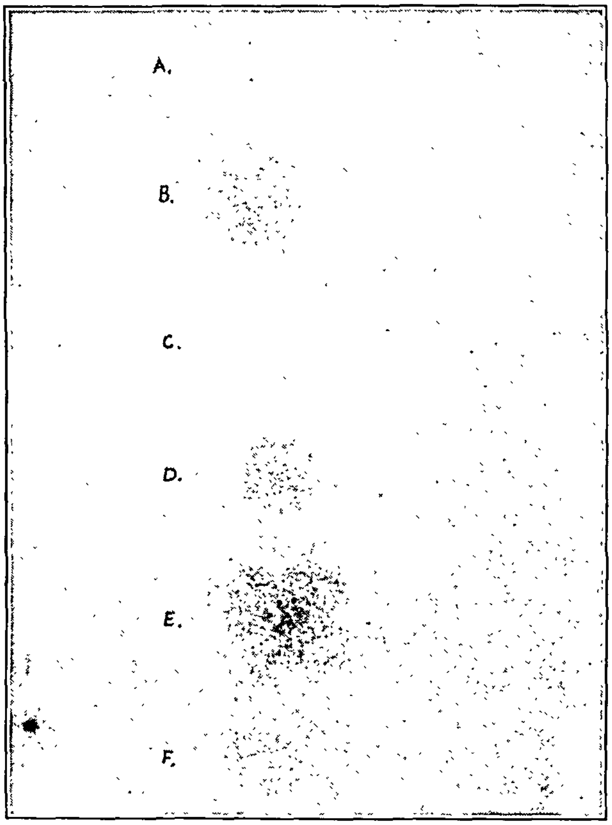

Fig. 5.—W. F., a 40 year old white man, had had a static ulcer on the right leg for eight years. At the initial visit, the ulcer was deeply stained with a red antiseptic. Patch tests were performed with (*A*) aqueous merthiolate,® (*B*) ammoniated mercury, (*C*) thiosalicylic acid, (*D*) mercresin,® (*E*) metaphen® and (*F*) mercuric chloride. All the reactions were positive except to thiosalicylic acid. The history disclosed that, to the patient's knowledge, mercresin® or metaphen® had never been applied to the ulcer. We cannot explain these groupings of reactions. Perhaps they are a mercury ion effect. The history did disclose that mercuric chloride, merthiolate® and ammoniated mercury had been used in treating the ulcer. This patient was not seen for the leg condition, but for a generalized dermatitis which appeared after application of merthiolate® to the ulcer.

B. Secondary or Generalized Signs Resulting from Primary Sensitization: In 11 out of 20 cases there developed a generalized dermatitis, the signs of which tended to reproduce the signs at the primary site of sensitization. The factor which apparently conditions a generalizing of the dermatitis is the application of the mercurial to the primary sensitization site.

*9. Patch Test Reactions.*—All reactions to patch tests with the mercurials indicate a generalized sensitization. Reactions that appear in less than twenty-four hours, and especially those associated with flaring, usually indicate a high degree of sensitization. These reactions are common in patients with generalized eruptions or patients who have had a generalized eruption from antiseptics in the past. Figure 4 illustrates a typical case.

---

[12] Howell, J. B.: Contact Dermatitis, Arch Dermat. & Syph. **53**: 265 (March) 1946.

*10. Exacerbation Time on Reexposure.*—If a patient experiences dermatitis in less than twenty-four hours on exposing an injured or normal skin to an organomercurial, it can be assumed that a preexisting sensitization was present. Obviously, the reexposure mercurial must be the same mercurial that induced the sensitization. Our investigations do not support multiple sensitivities to the organomercurials, but do support a remarkable specificity. A typical case is shown in figure 5.

*11. Complications.*—Proof of the sensitizing potency of the organomercurials is the fact that 11 patients out of 20 experienced generalized dermatitis. Five patients presented regional adenopathy, which adds significance to the reports [13] on the toxicity of mercurial antiseptics for embryonic tissue cells and leukocytes. In our series of cases, lymphangitis with adenopathy was frequently encountered as a complication of the primary sensitization signs at the site of injury. Do these antiseptics applied to injured skin destroy the natural defense mechanisms, thereby paving the way for bacterial or virus invasion; or is this complication a manifestation of sensitization? We suspect that merthiolate® has a highly selective toxicity for collagen and elastic tissue fibers.

*12. Remarks.*—Five of the 20 patients required hospitalization. No wonder the Council closed its report [4] on the organomercurials with this admonition, "It is a field in which wishful thinking is dangerous."

### INCIDENCE OF DERMATITIS VENENATA FROM APPLICATION OF ORGANOMERCURIALS TO DISEASED OR INJURED SKIN

Past treatment patch tests [1] performed on 400 dermatologic patients disclosed that 40 per cent (160 patients) experienced positive reactions to one or more of the remedies they had applied. The offender in 56 cases was one of the organomercurials, with merthiolate® being responsible for 90 per cent of the positive reactions.[2] Hopkins and his co-workers [14] treated 125 patients with dermatophytosis with the organomercurials and noted a 21 per cent incidence of irritation. Another series of 78 patients were treated with tincture of merthiolate® containing salicylic acid, 3 to 5 per cent. Now the incidence of irritation was 23 per cent. These reports appeared in October 1946, but in June 1944 these authors [15] in a discussion of treatment and prophylaxis of dermatophytosis advocated that every soldier showing evidence of dermatophytosis should be given preparations for self treatment, one of which was the merthiolate® salicylic acid combination. Observation of feet receiving this treatment prompted us to say, "The human foot has become the target of unbelievable chemical abuse." Howell [12] in a single year observed 25 cases of eczematous contact dermatitis from the use of topical mercurials. In 2 cases the condition was due to merthiolate® and in 1 case to mercurochrome.® During 1945, Ellis [101] encountered an additional 8 cases of dermatitis venenata from merthiolate.®

A report [3] on overtreatment dermatitis in dermatitis venenata due to plants disclosed that positive reactions to patch tests with various organomercurials were obtained in 113 cases. In these cases a dermatitis from plants had been changed into a mercurial eczematization by the injudicious use of antiseptics. Among the 113 patients having primary sensitization signs at the site of plant injury were 39 patients with toxic or sensitization "ids," 16 patients with lymphangitis and adenopathy and 6 patients with generalized dermatitis; 9 patients in the series had to be hospitalized.

### TOTAL INCIDENCE OF POSITIVE REACTIONS TO PATCH TESTS WITH ORGANOMERCURIAL COMPOUNDS OVER A THREE YEAR PERIOD

Past treatment patch tests [1] are a part of our workup in dermatologic patients. Practically as a routine, one or more mercurials are tested. This procedure, aside from being an important aid in diagnosis, has revealed the incidence of sensitization to mercury in patients with cutaneous diseases. From the point of view of dermatologic hygiene, this incidence is an appalling observation. The mercurials were applied to a wide range of cutaneous lesions. Already emphasized is the fact that a positive reaction to a patch test with a mercurial indicates a generalized sensitization. The incidence of primary sensitization signs at the site of injury, local irritative manifestations, without generalized sensitization, was doubtless significantly higher. The removal of the mercurial from these local or primary signs of sensitization obviously prevented a generalized sensitization.

Each patient was given patch tests with the mercurials they had applied to their cutaneous eruption, and, when feasible, additional organomercurials were tested with mercuric chloride as control. Patch tests with mercuric chloride aqueous, 0.1 per cent, were made in 579 cases; 29 single positive reactions occurred and a grouping of positive reactions in 60 cases. Mercuric chloride reacted simultaneously with ammoniated mercury in 15 cases, with merthiolate® tincture in 13 cases, with merthiolate® aqueous in 42 cases, with metaphen® in 1 case, with mercurochrome® in 4 cases and with mercocresols (mercresin®) in 7 cases. These figures suggest that the organomercurials on the skin (temperature, epithelium and secretions) readily dissociate, liberating mercury ions. The difference between the tincture and aqueous merthiolate® may be due to the presence of alcohol and eosin, retarding dissociation in the former. The single reactions cannot be explained except that they may indicate past mercurial contacts. The incidence of reactions to mercuric chloride was 15 per cent.

Eighty-nine patients were given patch tests with ammoniated mercury 5 per cent. Fifteen single positive reactions occurred, and in 26 cases there was grouping. Ammoniated mercury reacted with merthiolate® tincture in 5 cases, with merthiolate® aqueous in 9 cases, with metaphen® in 1 case, with mercurochrome® in 3 cases and with mercresin® in 4 cases. The incidence of reaction was 46 per cent. This is sufficiently high to exclude its use on diseased or injured skin by laymen. Patch tests with the tincture of merthiolate® were done in 238 cases; 9 single reactions occurred and 24 grouped. The tincture and aqueous merthiolate® reacted together in 15 cases. The incidence of positive reactions was 13 per cent. Patch tests with aqueous merthiolate® were done in 605 cases; 46 single reactions occurred, and in 57 there was grouping. The tendency to group reactions suggests that one mercurial on sensitizing the skin would also sensitize it to other organomercurials. Group reactions are better explained as past treatment exposures than as examples of multiple sensitivity. Positive reactions to patch tests with organomercurials are highly specific reactions. Ellis[101] stated the belief that the thiosalicylic acid radical is the usual sensitizing factor in merthiolate.® This radical would explain the single reactions to merthiolate® in the presence of negative reactions to mercuric chloride. Our data support the presence of two sensitizing factors in merthiolate.[3] Because venenata due to plants so violently disrupts the cutaneous protective barriers, it was stated that mercurial antiseptics were unsafe for self treatment of these dermatoses.[3] Twenty-five patients were tested with metaphen® with 5 single reactions and 2 grouped. The incidence was 28 per cent. Twenty-five patients were tested with mercurochrome,® with 2 single reactions and 4 grouped. The incidence was 24 per cent. Sixty-eight patients were tested with mercresin,® with 6 single reactions and 8 grouped. The incidence was 20 per cent.

Twelve years ago, Rostenberg and Sulzberger[16] observed an incidence of 17.8 per cent patch test reactions to ammoniated mercury, 2.4 per cent to mercurochrome,® 3 per cent to metaphen,® and 8.7 per cent to mercury bichloride. The greatest percentage of reactions occurred in the dermatitis venenata series of cases. Of far reaching importance from the point of view of dermatologic hygiene is this climbing incidence of dermatitis venenata from organomercurial compounds. Steps to prevent dermatitis have been falteringly taken, but an issue that requires a decision is whether, as physicians, we approve of mass sensitization to the mercurials. Mercurials readily produce dermal and epidermal sensitization. An inorganic mercurial, like calomel, has produced an explosive, generalized, urticarial, eczematized dermatitis in the presence of cutaneous sensitization to ammoniated mercury.[17] Perhaps, before mercurial diuretics are given it would be well to patch test with mercury to make sure no epidermal sensitization exists. Sudden death has followed the injection of mercurial diuretics.

## SUMMARY

The pharmacologic action of the organomercurials on normal and injured skin is presented as a part of the challenge on the therapeutic usefulness of these antiseptics.

# PERORAL ADMINISTRATION OF UNDECYLENIC ACID IN PSORIASIS

H. HARRIS PERLMAN, M.D.
and
IRVING L. MILBERG, M.D.
New York

In recent years, certain fatty acids have been found to exert antifungal activity on the human skin and to be valuable in both prevention and treatment of some of the superficial dermatomycoses.[1] As far as we have been able to discover, practically nothing is known to date about the pharmacologic, toxicologic and therapeutic potentialities of the oral administration of these acids. However, previous studies[2] appear to justify the assumption that a portion of an ingested amount of certain fatty acids may retain chemical characteristics in the fat of the tissue and in the sebum. The selection of an unsaturated acid appeared of special interest for the purposes of the present studies.

Our first attempts were designed to investigate the possibility that the oral administration of undecylenic acid might have a therapeutic effect on recalcitrant fungous infections, in particular on tinea capitis (Microsporon audouini) and on onychomycosis.

Preceding its administration to human beings, experiments on the toxicity of undecylenic acid were carried out on small laboratory animals. Large quantities of the acid were fed these animals daily over a period of many months without producing any toxic manifestations.[3]

After numerous trials with flavoring admixtures had failed, the disagreeable taste of the acid made it necessary to administer it to human beings in gelatin capsules.

Following a few, and certainly insufficient, clinical trials in tinea capitis and onychomycosis, one of us (H. P.) gave some of the acid by mouth to several

[3] The inner organs as well as the skin of 10 animals were examined histologically by Dr. F. G. Zak (Fellow in Dermatology and Syphilology, Post Graduate Medical School, New York University-Bellevue Medical Center). No significant alterations were encountered.

patients with psoriasis.[4] Dramatic improvements observed in a few patients in private practice prompted us to study the possible therapeutic action on a larger scope in psoriatic patients of the New York Skin and Cancer Unit. This report deals with a total of 41 patients treated to date.

At this point we wish to emphasize as strongly as we can that no therapeutic claims are being made for this new method. It is the purpose of this preliminary report to outline briefly, and with all reservations, some clinical impressions obtained thus far and to submit oral undecylenic acid therapy as a method for further study.

### CLINICAL MATERIAL

In order, as far as possible, to exclude false conclusions due to coincidental spontaneous remissions, the majority of the subjects chosen were psoriatic patients whose lesions had proved refractory to other recognized forms of therapy, or who had not had spontaneous remissions for a substantial period of time preceding the new approach. All external medications were excluded. Dietary and other habits prior to the period of treatment, such as bathing, remained essentially unchanged. The patients were examined at intervals of one to two weeks.

### DOSAGE AND SIDE EFFECTS

The dosage has varied considerably during the development of these studies. Initially, relatively small amounts had been administered, but during the course of the observation it became apparent that larger doses were both required and tolerated. The most recently adopted schedule is as follows: three times daily 5 pearls,[5] each containing 0.44 Gm. of undecylenic acid, continued for at least three days. Five pearls are taken between breakfast and lunch, 5 between lunch and supper and 5 before the patient goes to bed. Thereafter, 3 times 10 pearls are taken daily for at least another three days, and this is followed by 3 times 15 pearls daily, which is continued for an indefinite length of time. Both time intervals and dosage must be considered tentative and subject to future modifications.

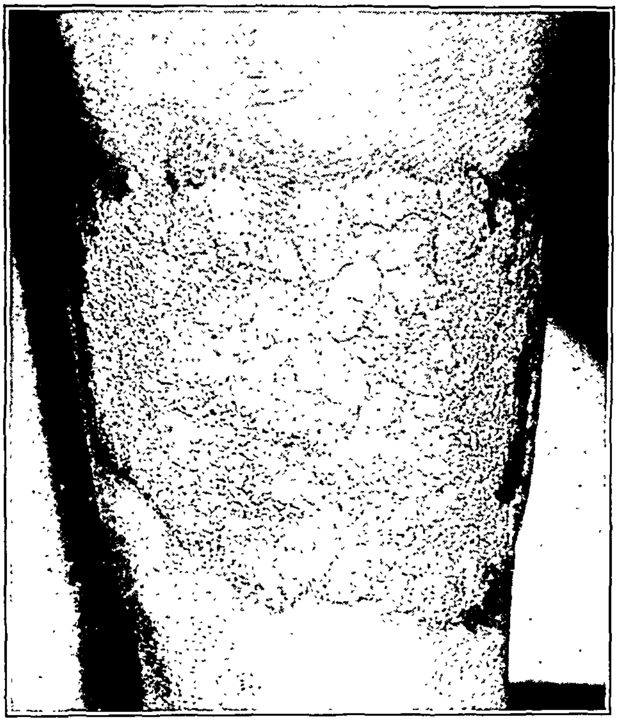

Fig. 1.—Hypertrophic psoriatic lesion on left calf of a 58 year old patient, which had been resistant for two years to topical treatments (chrysarobin, tar, ammoniated mercury, salicylic acid), liver injections, twelve roentgen treatments and ultraviolet irradiation.

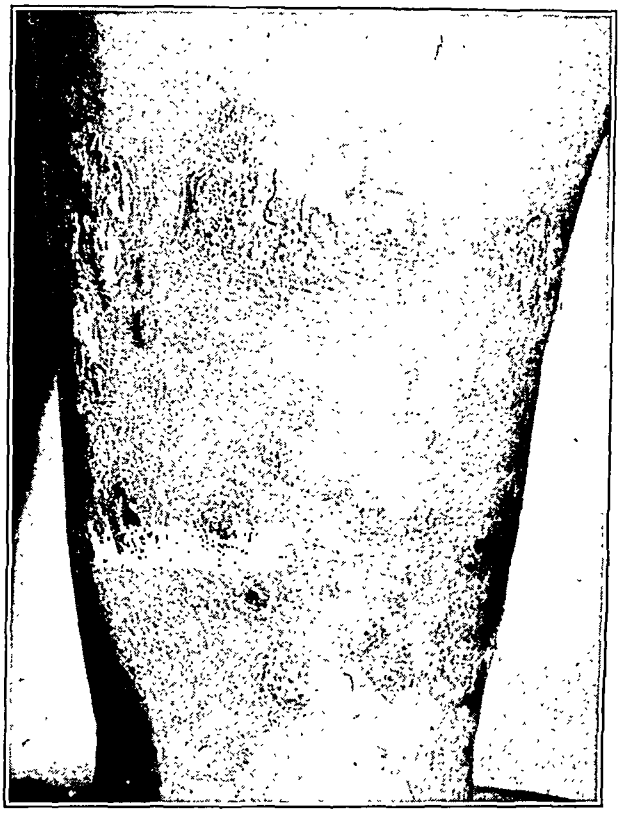

Fig. 2.—Same lesion as in figure 1, four months after the start of oral administration of undecylenic acid.

### RESULTS

No serious or lasting toxic effects were observed in this relatively small series. However, 19 of the 41 patients showed some symptoms or signs of mild gastrointestinal disturbance. Seven reported occasional eructations, with a peculiar "fishy" taste; 8 experienced nauseating sensations at times, and 2 complained of occasional vomiting. The stool became looser in most instances, and diarrhea occurred in 5 of the cases; constipation was present in 3. Some anorexia was noted by 5, and "heartburn" was occasioned in many of the patients.

In 2 young male patients, the occasional appearance of acneform follicular pustules was observed on the posterior aspect of the neck and on the thighs, but this may have been merely coincidental.

The described untoward effects were all transient. They occurred preponderantly at the onset of the treatment and usually subsided within seven to twenty-one days, even with continued administration of the same dose of the acid, without any, or with only mild and transitory recurrences during further increase in dosage. Thus, the early phase of the treatment and individual predisposition are apparently of greater significance for the occurrence of gastrointestinal disturbances than is the actual amount of undecylenic acid taken.

[5] The Decyl Pharmacal Company, Princeton, N. J., supplied this material. The pearls may be obtained from this firm as Declid® capsules.

In only 1 instance was the administration discontinued because of the intestinal complaints; this was in a female patient who complained of profuse diarrhea, beginning exceptionally late in treatment, namely, after twenty-three weeks (at this stage only one small lesion of psoriasis remained on the scalp).

### COURSE DURING TREATMENT

Two categories of clinical "improvement" are set up in this report. One, "improved," includes only cases with very substantial degrees of improvement; the other, "somewhat improved," includes cases with less impressive, though distinct, improvement. The former group is restricted to those cases in which the rate of improvement may perhaps have exceeded the range of any "spontaneous" involution which might occur in so erratic a disease as psoriasis. In the second group, i. e., that designated "somewhat improved," the occurrence of merely coincidental fluctuations of the picture (e. g., in some patients with eruptive forms of the disease) appeared possible in at least some of the cases. The table gives our results to date.

*Clinical Results* *

| | Number of Patients | Percentage |
|---|---|---|
| Improved | 12 | 30 |
| Somewhat improved | 15 | 37 |
| Unchanged | 10 | 25 |
| Worse | 3 | 7 |

*A total of 40 patients with skin lesions were treated for a period of two to twenty-seven weeks.

The shortest period of treatment after which unequivocal improvement ("improved") was recorded was two weeks; the longest period was two and a half months. In 3 cases of this group, the favorable course was preceded by a period of aggravation of the condition. New lesions had developed, and old ones had enlarged and become more intensely inflamed, before a sudden involution was observed. The earliest improvement in the "somewhat improved" group was noticed after two weeks and the latest after twelve weeks, followed gradually by further improvement.

Particularly in the "improved" group, some pattern in the process of involution could often be discerned. First, there was relief from any itching which may have been present, and thereupon flaky desquamation was noticeable, preponderantly in the central part of the lesions. Simultaneously, or very soon thereafter, the inner part of the plaques became flatter and paler, which was followed by the appearance of clinically normal, usually somewhat hyperpigmented, skin. Almost invariably, an annular zone at the periphery of the lesions showed the longest persistence; and finally the remaining ring-shaped walls around a clear center disintegrated into individual papules which were the last to disappear (figs. 1 and 2).

In 2 patients in the "improved" group, complete freedom from lesions was observed after two and a half months. The administration was continued in both cases for one month after the clearing, without any recurrence, and was then stopped. These patients at the time of writing were returning for observation.

In 2 patients in whom treatment was discontinued a few weeks after improvement had started (in one because of circumstances preventing attendance at clinic, in the other for purposes of trial), the psoriasis once more became aggravated and new papules appeared. With resumed administration, improvement was noted again.

### COURSE OF PSORIASIS WITH ARTHROPATHY

Among the 40 selected patients, 7 were suffering from psoriasis with arthropathy. One additional patient (a close relative of one of us) with psoriatic arthropathy, who was free from skin lesions at this time, was subjected to the same treatment. Seven of these 8 patients experienced decided relief from pain and from restriction of motility with the new treatment, while only slight, if any, improvement was noted by the remaining patient.

### COMMENT ON RESULTS

In a disease with a natural course as unpredictable as that of psoriasis, in a disease so well known to be capable of "spontaneous" remissions or favorable response to any new approach at any time, attempts to evaluate a new therapeutic method may easily lead to erroneous impressions. This holds true, in particular, when the number of patients is as small as in the present series. However, the described unequivocal improvement in 30 per cent of psoriatic patients, most of whom suffered from a stubborn form of the disease, would make it appear somewhat unwise to assume that these results were all merely coincidental. The relapses observed in 2 instances during interruptions of the treatment, and the renewed improvements with its resumption, favor the hypothesis that the medication might have exerted some beneficial influence.

Though much more experience is necessary before definite conclusions can be drawn, the present results appear to us to warrant the encouragement of other dermatologists to study this form of medication. It is certain that more adequate control series are needed in which the effects of purging alone are examined, as well as controls treated with therapeutically inert administrations, e. g., "placebo" pearls. Investigations along these lines are now in progress.

### RATIONALE

No rationale underlying the new therapeutic approach can be offered at this early stage of the investigations. The possible connection between the effects of fatty acid administration and the widely postulated, but still obscure, disturbance in lipid metabolism,[6] with the accumulation of fat manifested histologically in the skin of psoriatic persons,[7] immediately springs to mind. There may also be some relation to the regimens of antipsoriatic treatment which restrict the intake of animal fat, or which introduce lipotropic substances, as suggested by earlier investigators.[8]

### REACTIVE HYPEREMIA TEST

The apparently significant role of vascular function in the pathogenesis of psoriatic lesions[9] prompted one of us (I. L. M.) to continue his earlier examinations[10] of the vascular response of clinically uninvolved skin to a mechanical stimulus in psoriatic patients, and in particular to follow up carefully this response in the patients receiving undecylenic acid. The method of DiPalma, Reynolds and Foster[11] was employed (reactive hyperemia test). It is pertinent to remember that there is a seasonal variation in all the readings obtained. The length of time necessary to produce the appearance of erythema, i. e., the "threshold response," in healthy persons, progresses from an average of 20 seconds in July to 70 seconds in January, and then gradually returns to 20 seconds by the end of June. The reactive hyperemia tests were performed before treatment with undecylenic acid was begun and repeated at each subsequent visit during the course of treatment. The results of the tests preceding treatment were in full agreement with the observations reported previously.[9c] In all patients with psoriasis the time required to elicit reactive hyperemia, that is, the stimulus time or the threshold, greatly exceeded the corresponding time in healthy persons. The results changed during the course of treatment in distinct conformity with the progress of the disease; namely, the readings invariably approached the normal range of stimulus time as the lesions improved, but remained high or rose when the disease remained unchanged or became aggravated. In fact, the results of this test almost regularly preceded the corresponding changes in the clinical course, so that the test became a valuable aid in prognosis. The following compilation presents a condensed review of these observations in the present series in which the total number of readings in psoriasis patients was 334 and in clinically healthy persons (controls) 122.

| | Time, Seconds |

### SUMMARY

Forty-one psoriatic patients were treated with undecylenic acid perorally. Many of these patients were suffering from recalcitrant forms of the disease. No external medication was used.

The standard dose eventually adopted, which was also the highest daily dosage attained, was 19.8 Gm. of the acid, in the form of 45 pearls of 0.44 cc. each, i. e., 3 times 15 pearls per day. The ingestion was found free from serious or lasting toxic effects. Mild gastrointestinal disturbances occurred, but only in 1 instance did these interfere with the continuation of the treatment schedule.

Of 40 psoriatic patients with cutaneous lesions, 12 showed unequivocal improvement during treatment, 15 were somewhat improved, 10 evidenced no change and 3 had distinct aggravation of the disease. Seven of 8 patients with psoriatic arthropathy noted relief from pain.

It appears possible that the undecylenic acid had favorable influence on the course of some of the cases in the improved group observed. Much further investigation will be needed before definite conclusions can be drawn. The object of this report is to submit the method and its many possible modifications for more extensive clinical evaluation and further fundamental study.

# ON ALLERGY TO COTTONSEED OIL

H. S. BERNTON, M.D.
E. J. COULSON, Ph.D.
and
HENRY STEVENS, Ph.D.
Washington, D. C.

The question of specific sensitiveness to edible cottonseed oil in contradistinction to cottonseed is worthy of recognition and more critical study than it has received. Discussions of cottonseed sensitiveness in textbooks on allergy generally imply that cutaneous sensitiveness to allergenic extracts of cottonseed or cottonseed meal signifies clinical sensitiveness to foods containing salad oil or vegetable shortening made from cottonseed oil. A pronounced difference of opinion concerning this concept is displayed in the testimony of six allergists who appeared as expert witnesses at a public hearing[1] in relation to label declaration of vegetable oils in salad dressings.

Opportunity to study allergy to cottonseed oil is rare.[1] Hence, worthy of record are results of a concurrent comparison of two cottonseed-sensitive allergic subjects, one of whom disclaimed and the other proclaimed a demonstrable sensitiveness to edible cottonseed oil.

## REPORT OF CASES

CASE 1.—A male asthmatic patient (S.), age 34, exhibited multiple sensitiveness in cutaneous tests with several allergens, including cotton and cottonseed. His clinical history showed convincingly negative reactions to cottonseed oil. This conclusion was confirmed by oral administration, under observation, of 1 fluidounce (29.6 cc.) of cottonseed salad oil. Ingestion of this dose three hours after breakfast induced no immediate or delayed symptoms. At a later visit a specimen of blood was taken from this patient, the source of serum S.

CASE 2.—An allergic subject (O.) was not examined in person, but his own diagnosis of his sensitiveness to cottonseed was accepted and is reported without prejudice in acknowledgment of his respected standing as an allergist of extensive clinical and research experience.

The family history of this subject is positive for allergy. Hay fever, identified with pollen sensitivity, developed in 1930. Two years later he was afflicted with hives, which could be induced by trial contact with nonabsorbent cotton or by sleeping on a cotton-filled mattress. At this time, abdominal discomfort, which he attributed to ingestion of foods containing hydrogenated vegetable oil shortenings, led him to suspect a pronounced sensitiveness to edible cottonseed oil. This diagnosis, he concluded, was confirmed by his positive reactions to cutaneous tests with cottonseed extract. Clinical sensitiveness to several other foods became evident in 1943, proved by dietary trial and elimination from the diet. However, only his clinical evidence in support of the diagnosis of his acute allergic sensitiveness to cottonseed oil is pertinent to the present study.

This subject endeavored to exclude from his diet any food that might contain cottonseed oil or hydrogenated cottonseed oil even as an ingredient of the least proportion. Allergic symptoms resulting from unintentional ingestion of such foods were hives, prolonged abdominal distress, including acute griping pain, and diarrhea. These symptoms could be relieved or diminished with antihistaminic drugs.

In contrast to the invariable allergic reaction resulting from eating foods containing cottonseed oil, this subject stated that ingestion of corn oil or olive oil caused him no distress. These oils were regularly used in his home. He was confident, therefore, that he could distinguish cottonseed oil from corn oil or olive oil by the consistent occurrence of perceptible allergic symptoms whenever he ingested even a comparatively small quantity of cottonseed oil. But he was reluctant to undergo the discomfort required to demonstrate this capacity. Fortunately, however, this subject was keenly interested in our studies of allergens of cottonseed products and complied with our request for his collaboration. On Jan. 3, 1948, we received from him a quantity of his blood serum, which is identified as serum O. Subsequently, he served as subject for a succession of discrimination trials to test his capacity to distinguish cottonseed oil by his symptoms of allergy.

## PASSIVE TRANSFER TESTS (SERUM S AND SERUM O)

Serum S and Serum O were investigated in comparative tests for reagins for cottonseed oil and for cottonseed. Reactivity of passively sensitized sites was determined by intracutaneous tests with cotton seed oil and with allergenic extracts of defatted cottonseed and, also, by oral administration of both oil and defatted cottonseed.

Nine recipients were given an intracutaneous injection in the left upper arm with 0.1 cc. of serum O. After an interval of three or more days, four sites were tested with 0.025 cc. of sterile cottonseed oil; three sites were tested with 0.01 mg. of CS-1A (an active protein component of cottonseed)[2]; and two sites were tested with unfractionated cottonseed extract (1:50,000). The skin of the anterior surface of the lower arm served for control injections. The controls and all passively transferred sites gave negative reactions in these tests.

Five recipients were sensitized with 0.1 cc. each of serum S and serum O in each upper arm. The sites were separated by about 2 inches (5 cm.). Four days later one serum S site and one serum O site on each of the 5 recipients were tested with an intracutaneous injection of cottonseed oil. All results were negative. One serum S site and one serum O site on each of 3 recipients were tested with cottonseed extract. The three serum S sites gave vigorous positive reactions. All three serum O sites were inactive. One serum S site and one serum O site on each of the 2 remaining recipients were tested with CS-1A. The two serum S sites gave vigorous positive reactions; both serum O sites gave negative reactions.

For the tests by oral administration, 5 subjects were sensitized in the left upper arm with 0.1 cc. of serum S and in the right upper arm with 0.1 cc. of serum O. Three subjects, members of our laboratory staff, were similarly sensitized with 0.05 cc. of the respective serums. All subjects were advised to avoid food products containing cottonseed oil for the duration of the experiment. One to three days later, with fasting stomach, 3 of the subjects drank 60 cc. and 3 subjects drank 100 cc. of cottonseed oil. They were kept under observation for one hour or more. There was no itching, swelling, or redness at the passively sensitized sites.

Two of the subjects refused to take the oil. Accordingly, their sensitized sites were tested intracutaneously with cottonseed oil, with negative results.

Six days after the ingestion of the 100 cc. dose of cottonseed oil, each of the 3 laboratory personnel

## REACTIVE HYPEREMIA TEST

The apparently significant role of vascular function in the pathogenesis of psoriatic lesions[9] prompted one of us (I. L. M.) to continue his earlier examinations[10] of the vascular response of clinically uninvolved skin to a mechanical stimulus in psoriatic patients, and in particular to follow up carefully this response in the patients receiving undecylenic acid. The method of DiPalma, Reynolds and Foster[11] was employed (reactive hyperemia test). It is pertinent to remember that there is a seasonal variation in all the readings obtained. The length of time necessary to produce the appearance of erythema, i. e., the "threshold response," in healthy persons, progresses from an average of 20 seconds in July to 70 seconds in January, and then gradually returns to 20 seconds by the end of June. The reactive hyperemia tests were performed before treatment with undecylenic acid was begun and repeated at each subsequent visit during the course of treatment. The results of the tests preceding treatment were in full agreement with the observations reported previously.[9c] In all patients with psoriasis the time required to elicit reactive hyperemia, that is, the stimulus time or the threshold, greatly exceeded the corresponding time in healthy persons. The results changed during the course of treatment in distinct conformity with the progress of the disease; namely, the readings invariably approached the normal range of stimulus time as the lesions improved, but remained high or rose when the disease remained unchanged or became aggravated. In fact, the results of this test almost regularly preceded the corresponding changes in the clinical course, so that the test became a valuable aid in prognosis. The following compilation presents a condensed review of these observations in the present series in which the total number of readings in psoriasis patients was 334 and in clinically healthy persons (controls) 122.

# ON ALLERGY TO COTTONSEED OIL

H. S. BERNTON, M.D.
E. J. COULSON, Ph.D.
and
HENRY STEVENS, Ph.D.
Washington, D. C.

The question of specific sensitiveness to edible cottonseed oil in contradistinction to cottonseed is worthy of recognition and more critical study than it has received. Discussions of cottonseed sensitiveness in textbooks on allergy generally imply that cutaneous sensitiveness to allergenic extracts of cottonseed or cottonseed meal signifies clinical sensitiveness to foods containing salad oil or vegetable shortening made from cottonseed oil. A pronounced difference of opinion concerning this concept is displayed in the testimony of six allergists who appeared as expert witnesses at a public hearing[1] in relation to label declaration of vegetable oils in salad dressings.

Opportunity to study allergy to cottonseed oil is rare.[1] Hence, worthy of record are results of a concurrent comparison of two cottonseed-sensitive allergic subjects, one of whom disclaimed and the other proclaimed a demonstrable sensitiveness to edible cottonseed oil.

## REPORT OF CASES

CASE 1.—A male asthmatic patient (S.), age 34, exhibited multiple sensitiveness in cutaneous tests with several allergens, including cotton and cottonseed. His clinical history showed convincingly negative reactions to cottonseed oil. This conclusion was confirmed by oral administration, under observation, of 1 fluidounce (29.6 cc.) of cottonseed salad oil. Ingestion of this dose three hours after breakfast induced no immediate or delayed symptoms. At a later visit a specimen of blood was taken from this patient, the source of serum S.

CASE 2.—An allergic subject (O.) was not examined in person, but his own diagnosis of his sensitiveness to cottonseed was accepted and is reported without prejudice in acknowledgment of his respected standing as an allergist of extensive clinical and research experience.

The family history of this subject is positive for allergy. Hay fever, identified with pollen sensitivity, developed in 1930. Two years later he was afflicted with hives, which could be induced by trial contact with nonabsorbent cotton or by sleeping on a cotton-filled mattress. At this time, abdominal discomfort, which he attributed to ingestion of foods containing hydrogenated vegetable oil shortenings, led him to suspect a pronounced sensitiveness to edible cottonseed oil. This diagnosis, he concluded, was confirmed by his positive reactions to cutaneous tests with cottonseed extract. Clinical sensitiveness to several other foods became evident in 1943, proved by dietary trial and elimination from the diet. However, only his clinical evidence in support of the diagnosis of his acute allergic sensitiveness to cottonseed oil is pertinent to the present study.

This subject endeavored to exclude from his diet any food that might contain cottonseed oil or hydrogenated cottonseed oil even as an ingredient of the least proportion. Allergic symptoms resulting from unintentional ingestion of such foods were hives, prolonged abdominal distress, including acute griping pain, and diarrhea. These symptoms could be relieved or diminished with antihistaminic drugs.

In contrast to the invariable allergic reaction resulting from eating foods containing cottonseed oil, this subject stated that ingestion of corn oil or olive oil caused him no distress. These oils were regularly used in his home. He was confident, therefore, that he could distinguish cottonseed oil from corn oil or olive oil by the consistent occurrence of perceptible allergic symptoms whenever he ingested even a comparatively small quantity of cottonseed oil. But he was reluctant to undergo the discomfort required to demonstrate this capacity. Fortunately, however, this subject was keenly interested in our studies of allergens of cottonseed products and complied with our request for his collaboration. On Jan. 3, 1948, we received from him a quantity of his blood serum, which is identified as serum O. Subsequently, he served as subject for a succession of discrimination trials to test his capacity to distinguish cottonseed oil by his symptoms of allergy.

## PASSIVE TRANSFER TESTS (SERUM S AND SERUM O)

Serum S and Serum O were investigated in comparative tests for reagins for cottonseed oil and for cottonseed. Reactivity of passively sensitized sites was determined by intracutaneous tests with cotton seed oil and with allergenic extracts of defatted cottonseed and, also, by oral administration of both oil and defatted cottonseed.

Nine recipients were given an intracutaneous injection in the left upper arm with 0.1 cc. of serum O. After an interval of three or more days, four sites were tested with 0.025 cc. of sterile cottonseed oil; three sites were tested with 0.01 mg. of CS-1A (an active protein component of cottonseed)[2]; and two sites were tested with unfractionated cottonseed extract (1 : 50,000). The skin of the anterior surface of the lower arm served for control injections. The controls and all passively transferred sites gave negative reactions in these tests.

Five recipients were sensitized with 0.1 cc. each of serum S and serum O in each upper arm. The sites were separated by about 2 inches (5 cm.). Four days later one serum S site and one serum O site on each of the 5 recipients were tested with an intracutaneous injection of cottonseed oil. All results were negative. One serum S site and one serum O site on each of 3 recipients were tested with cottonseed extract. The three serum S sites gave vigorous positive reactions. All three serum O sites were inactive. One serum S site and one serum O site on each of the 2 remaining recipients were tested with CS-1A. The two serum S sites gave vigorous positive reactions; both serum O sites gave negative reactions.

For the tests by oral administration, 5 subjects were sensitized in the left upper arm with 0.1 cc. of serum S and in the right upper arm with 0.1 cc. of serum O. Three subjects, members of our laboratory staff, were similarly sensitized with 0.05 cc. of the respective serums. All subjects were advised to avoid food products containing cottonseed oil for the duration of the experiment. One to three days later, with fasting stomach, 3 of the subjects drank 60 cc. and 3 subjects drank 100 cc. of cottonseed oil. They were kept under observation for one hour or more. There was no itching, swelling, or redness at the passively sensitized sites.

Two of the subjects refused to take the oil. Accordingly, their sensitized sites were tested intracutaneously with cottonseed oil, with negative results.

Six days after the ingestion of the 100 cc. dose of cottonseed oil, each of the 3 laboratory personnel

[1] Allergy to Cottonseed and Other Oil Seeds and Their Edible Derivatives, excerpts from testimony before the Administrator, Federal Security Agency, Docket FDC-51, Public Hearings Held at Washington, D. C., Nov. 18, 1947 and Jan. 6-8, 1948 (Memphis, Tenn., National Cottonseed Products Association, Inc., 1948).

[2] Spies, J. R.; Coulson, E. J.; Bernton, H. S., and Stevens, H.: The Chemistry of Allergens: II. Isolation and Properties of an Active Protein Component of Cottonseed, J. Am. Chem. Soc. **62**: 1420 (June) 1940.

ingested 10 Gm. of defatted cottonseed in water. Whealing became perceptible on the left arm, at the serum S site, eight, fifteen and twenty-seven minutes, respectively, after ingestion. The serum O sites remained inactive.

Table 1.—*Discrimination Trials, Series I*

| Vial | Submitted | Response | Net Dose and Identity of Sample |
|---|---|---|---|
| E | April 1 | Positive | No cottonseed oil; 4.1 Gm. corn oil |
| H | April 5 | Negative | No cottonseed oil; 4.0 Gm. corn oil |
| F | April 12 | Negative | 0.6 Gm. cottonseed oil; 3.5 Gm. corn oil |
| A | April 19 | Positive | No cottonseed oil; 3.9 Gm. corn oil |
| D | April 26 | Negative | No cottonseed oil; 3.9 Gm. corn oil |
| B | May 3 | Negative | 0.6 Gm. cottonseed oil; 3.3 Gm. corn oil |
| C | ........ | .......... | No cottonseed oil; ... ..... corn oil |
| G | ........ | .......... | No cottonseed oil; ... ..... corn oil |

Results of the passive transfer tests were consistent. The presence of reagin for cottonseed was demonstrated in serum S; the absence of this reagin was proved for serum O. Each site sensitized with serum S reacted positively whether the water-soluble allergen of the cottonseed embryo was administered by direct injection into the sensitized site or by ingestion, while none of the sites sensitized with serum O showed any perceptible response. The tests employed failed to show the presence of a reagin for cottonseed oil in either serum S or serum O. After these tests were completed subject O (case 2) reported that he reacted negatively to cutaneous tests with corn oil, cottonseed oil and CS-1A, but an intracutaneous test with his own cottonseed extract elicited a positive reaction.

### TESTS OF DISCRIMINATIVE CAPACITY

Three series of ingestion trials were conducted to test the capacity of subject O to discriminate between samples of vegetable oil that were alike in color, viscosity, flavor and odor, but which differed with respect to the presence or absence of cottonseed oil. Series I and II were designed to yield statistically significant evidence of discrimination, or lack of it. Series III was designed to find the subject's threshold of allergic response to cottonseed oil.

Table 2.—*Discrimination Trials, Series II*

| Vial | Submitted | Response | Net Dose and Identity of Sample |
|---|---|---|---|
| K | May 18 | Negative | 2.1 Gm. corn oil; 2.1 Gm. olive oil |
| N | May 24 | Negative | 1.9 Gm. corn oil; 1.9 Gm. olive oil |
| O | June 1 | Negative | 2.2 Gm. cottonseed oil; 2.2 Gm. olive oil |
| J | June 7 | Positive | 2.0 Gm. corn oil; 2.0 Gm. olive oil |
| M | June 14 | Negative | 1.9 Gm. cottonseed oil; 1.9 Gm. olive oil |
| I | June 21 | Negative | 2.0 Gm. corn oil; 2.0 Gm. olive oil |
| P | June 28 | Negative | 1.9 Gm. corn oil; 1.9 Gm. olive oil |
| L | July 6 | Negative | 1.2 Gm.* cottonseed oil; 1.2 Gm.* olive oil |

* About one third of sample spilled; net dose was estimated.

Corn oil, cottonseed oil and olive oil used in these trials were purchased at retail and represent familiar brands of these salad oils. The manufacturer's representation of identity of each oil was confirmed. Each oil met the standards prescribed for it by the United States Pharmacopeia XIII.

Individual samples of each series were matched in appearance by addition of butter color. Samples comprising each series were judged by three chemists to be indistinguishable in taste and appearance. Series I and II were submitted in 4 cc. vials, each containing a single trial dose of about 4 Gm. of oil. For series III, 7.5 cc. vials were used to provide a range of larger doses of cottonseed oil.

In each series both the distribution of the samples containing cottonseed oil and the order of presentation of samples were randomized. The subject was told in advance of the trials the number of samples to be submitted in each series, the approximate dose and the number of times cottonseed oil might be encountered. Neither the subject nor the dispenser of the vials was informed of the composition of the individual samples until the last report of each series had been recorded.

The subject complied with our instructions to ingest each sample without other food when free from symptoms of allergy. He returned each emptied vial with a report of his decision, positive or negative, to indicate presence or absence of cottonseed oil, according to his perception of allergic response. Each succeeding sample, after the first one of series I and II, was submitted on return of the emptied vial of the preceding sample. The net weight of each sample ingested and the net dose of cottonseed oil were calculated from the difference in weights of each filled and emptied vial.

Table 3.—*Discrimination Trials, Series III**

| | | | Cottonseed Oil | |
|---|---|---|---|---|
| Subject's Comment | Subject's Decision | Vial | Gm. | Percentage |
| Not the slightest discomfort (no. 4, 5, 6) or no recollection of discomfort (no. 8). Definitely negative | Definitely negative, no. 4,5,6,8 | 4<br>5<br>6<br>8 | None<br>3.6<br>None<br>1.9 | <br>50<br><br>25 |
| Slight, transient abdominal discomfort; ignored unless looking for symptoms. Not quite definitely negative | Qualified negative, no. 1,2,9 | 1<br>2<br>9 | 7.3<br>3.6<br>5.6 | 100<br>50<br>75 |
| Abdominal pain mild but noticeable, lasting to one-half hour. Reaction from no. 0 was more than from no. 3. Considered doubtful positive reactions | Qualified positive, no. 0,3 | 0<br>3 | 1.9<br>5.6 | 25<br>75 |
| Definitely positive reactions. Prompt appearance (10 min.) of moderate to severe abdominal pain, persisting for 1 hour or more. Unquestionably positive reactions | Definitely positive, no. 7,10 | 7<br>10 | 1.9<br>3.6 | 25<br>50 |

* Order of ingestion of samples: No. 10, 6, 7, 4, 2, 1, 9, 3, 5, 8, 0.

The last two samples of series I were not submitted because the results of the preceding six trials provided convincing evidence of inability of the subject to distinguish cottonseed oil in dosage of 0.6 Gm. When this evidence was presented to the subject he concluded that he was less sensitive to cottonseed oil than he had presumed. Accordingly, he agreed to try another series in which a larger dose of cottonseed oil would be included in two or three of eight samples. For benefit of flavor the samples of series II were composed either of equal parts of olive oil and corn oil or olive oil and cottonseed oil.

Results of series II provided conclusive evidence that the subject did not distinguish cottonseed oil when ingested in doses corresponding to quantities of this fat commonly encountered in a dietary portion of staple food—salad or bread, for example. This evidence prompted the subject to propose a trial to establish his threshold of allergic sensitiveness to cottonseed oil. Series III was designed for that purpose.

Eleven samples of series III were submitted to the subject with the information that they were composed of samples of corn oil, and mixtures of corn and cottonseed oil that provided net doses of cottonseed oil in a range within and above the quantities ingested in the preceding series. Because series III was designed to establish the threshold of allergic response to cottonseed oil, the subject chose to qualify his response to each trial. His responses are classified and summarized in table 3.

Results of series III provided no evidence of discrimination consistently relatable to net dosage of cottonseed oil. Therefore, no evidence is deducible from these data of a threshold of sensitiveness to an allegedly allergenic component of the samples composed of corn and/or cottonseed oil. This series provided two samples of 7.3 Gm. of corn oil and the following net doses of cottonseed oil: three of 1.9 Gm., three of 3.6 Gm., two of 5.6 Gm. and one of 7.3 Gm.

## COMMENT

Two cottonseed-sensitive allergic subjects have been studied. They both exhibited cutaneous sensitiveness to aqueous extracts of defatted cottonseed and to cotton. With respect to evidence of clinical sensitiveness to edible cottonseed oil these subjects, S and O, represent opposite extremes. Subject S reported no symptoms suggestive of clinical sensitiveness to cottonseed oil. On the other hand, subject O supported his own positive diagnosis by a clinical history clearly indicative of a high degree of allergic sensitiveness to cottonseed oil. A unique opportunity was afforded by the coincident availability of these subjects to investigate relationships between cutaneous sensitiveness to allergenic extracts of the cottonseed embryo, and clinical sensitiveness to the edible oil derived from this part of the seed.

Comparison of serums of subject S and subject O by passive transfer technic demonstrated the reagin for cottonseed only in serum S. No evidence of sensitiveness to cottonseed oil was manifested in either subject by direct cutaneous or passive transfer tests with the oil. Oral administration of cottonseed oil to subject S confirmed his opinion that ingestion of this oil caused no perceptible reaction. Collaboration of subject O enabled us to conduct discrimination trials designed to test the validity of the clinical evidence of his sensitiveness to ingested cottonseed oil. These trials yielded conclusive evidence that he could not distinguish cottonseed oil from corn oil or olive oil by perception of allergic symptoms when he ingested samples containing cottonseed oil. Therefore, his diagnosis of clinical sensitiveness to cottonseed oil was not substantiated.

Results of our comparison of 2 cottonseed-sensitive subjects are relevant to certain of our previously reported investigations dealing with immunologic properties of cottonseed products. In 1940, Bernton, Spies and Stevens[3] described a series of experiments which led to the following conclusions: (1) that edible cottonseed oil does not contain the water-soluble cottonseed allergen which is readily extractable from the defatted cottonseed kernel (embryo) or from commercial cottonseed flour or meal and, (2) that cutaneous sensitiveness to such extracts does not imply clinical sensitiveness to cottonseed oil. Later, Coulson and Stevens[4] reported the preparation of water-soluble antigenic fractions from widely different grades of cotton linters. Neither the higher grade of linters, which was essentially free from visible hull material, nor the lower grade, which was heavily laden with hull particles, contained the cottonseed antigen. These observations clearly distinguished the water-soluble antigen of the seed hairs from that of the cottonseed embryo. This distinction between antigens of different tissues of the entire ginned cottonseed justifies the inference that a corresponding distinction may be anticipated with respect to clinical sensitiveness to cotton linters and to cottonseed flour or meal. At least, substantial confirmatory evidence should be expected to support a claim of immunologic interrelationship in clinical sensitiveness to essentially different commodities derived from cottonseed.

In 1942 Figley[5] reported his study of 2 cases of suspected sensitiveness to cottonseed and cottonseed oil. A tentative diagnosis of sensitiveness to the water-soluble seed allergens was not substantiated for either case by direct or by passive transfer tests. For both cases, however, the diagnosis of clinical sensitiveness to cottonseed oil appeared to be substantiated by results of a few ingestion trials, which, for one of the patients, were conducted in collaboration with one of us (H. S.). Subsequent study of both patients by Figley generated doubt about this diagnosis. Justifiable skepticism has since been expressed by Figley[1] concerning the adequacy of the published data[5] for proof of clinical sensitiveness to cottonseed oil in either of these cases. Consequently, these 2 cases must be classed with those reported in the literature, and in legend, for which the diagnosis of clinical sensitiveness to ingested cottonseed oil lacks substantial confirmatory evidence. While allergy to ingested cottonseed oil may exist, no case on record has been found for which this diagnosis has been confirmed by conclusive, scientific evidence.

## SUMMARY AND CONCLUSIONS

Two cottonseed-sensitive allergic cases have been compared with reference, principally, to diagnostic criteria of clinical sensitiveness to edible cottonseed oil. In 1 case, the diagnosis of specific sensitiveness to cottonseed, with no implied sensitiveness to ingested cottonseed oil, was corroborated by evidence derived from passive transfer studies and demonstration of tolerance to a liberal dose of cottonseed oil. In the other case, the diagnosis of clinical sensitiveness to ingested cottonseed oil was not confirmed. No evidence of discrimination was displayed by the subject when he endeavored to distinguish cottonseed oil solely by his perception of allergic reaction to ingested doses in the range of 0.6 to 7.3 Gm. Comparative study of these cases adds supporting evidence to the conclusion that specific sensitiveness to water-soluble, allergenic extracts of defatted cottonseed (embryo) does not imply clinical sensitiveness to edible cottonseed oil.

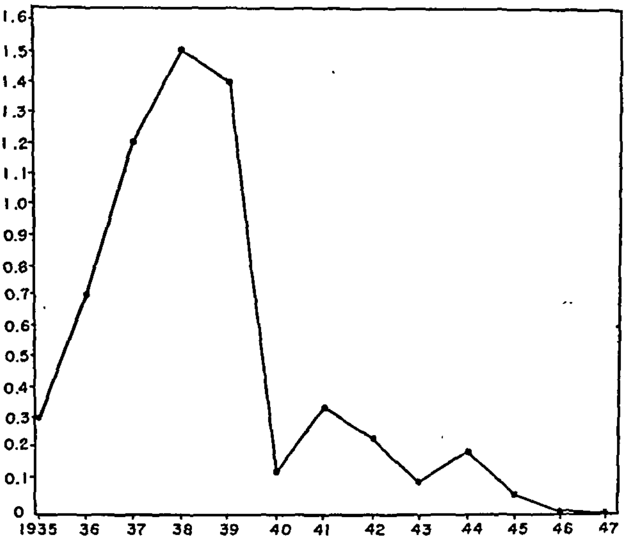
# INCIDENCE OF PELLAGRA

## Studies in the Cincinnati General Hospital 1935-1947

WILLIAM B. BEAN, M.D.
RICHARD W. VILTER, M.D.
and
MARION A. BLANKENHORN, M.D.
Cincinnati

In 1942 Bean, Spies and Blankenhorn[1] pointed out that, far from being an exotic disease, pellagra was relatively common in hospitals in Cleveland and Cincinnati during a period when an intensive study of nutritional disease was in progress. At the Lakeside Hospital, Cleveland, initial admissions for pellagra constituted 1.5 per cent of all medical ward admissions from 1930 to 1935, while at the Cincinnati General Hospital such cases constituted 0.95 per cent of medical admissions from 1935 to 1939. These figures were compared with those reported from the Baltimore City Hospital, Charity Hospital (New Orleans), Hillman Hospital (Birmingham, Ala.), University of Georgia Hospital (Augusta) and the Duke Hospital. It is the purpose of the present paper to extend the data on admissions for pellagra at the Cincinnati General Hospital through 1947 and discuss the sharp decrease in incidence.



Incidence of pellagra expressed as percentage of all medical ward admissions (vertical values) 1935-1947. The years are shown in the horizontal row of figures.

SUBJECTS AND CRITERIA

We have included in our analysis all cases of patients presenting bilateral pellagrous dermatitis and glossitis, since these criteria for diagnosis were used in the earlier paper.[1] Only patients seen by at least one of us were used, and there was complete agreement regarding the diagnosis in all cases observed by more than one of us. One or more of us was in close touch with the wards at all times during the study, and many patients suspected of having some variety of malnutrition were brought to our notice by members of the house staff. Efforts to find all cases of vitamin deficiency in the hospital continued without intermission. Only patients admitted or transferred to the medical wards are included. Consultation regarding the possible diagnosis of pellagra on other wards brought in only a few cases. We have no reason to believe that alterations in requirements for hospital admission, shifts in population or other circumstances have produced any significant influence in the remarkable change in the incidence of florid pellagra in this hospital. Whereas we suspected that the rather abrupt rise in the number of cases of pellagra reported previously[1] reflected to some degree the increase in diagnostic skill and awareness, we do not consider that the sharp decline in incidence signifies a decline in interest or diagnostic ability.

RESULTS

In the figure and in the table we present the data on initial admissions for pellagra for the years 1935-1947 inclusive. The most striking feature of the changing yearly incidence is the precipitous drop in the number of cases of pellagra from 1939 to 1940, when the total number of cases fell from 34 to 3. This did not represent an isolated experience, since the low rate of admission for pellagra continued with minor fluctuations through 1947. In 1946 and 1947 there were no cases of pellagra on the medical wards, and only 1 patient had been seen through July 1948.

A similar decrease occurred in the frequency with which the diagnosis of nicotinic acid deficiency was made, though our records are not complete in this regard.

COMMENT

The facts presented demonstrate that pellagra was disappearing from the wards of the Cincinnati General Hospital during a period when an intensive program of nutritional investigation was in progress and an active search for cases was going on. We believe that no lapse of interest or change in requirement for hospital admission has produced an artificial bias in the figures. A consideration of pertinent factors which may have had a part in causing this decrease in cases of pellagra has been made without the assurance that the true explanation has been found. We will discuss the possible influences of the general economic state of the community, employment, the war, rationing, education, bread enrichment, alcohol addiction and self medication with vitamins.

It is impossible to find any true measure of the relative or absolute changes in the general economic situation of the clientele of the hospital. As a rough approximation, the index of industrial employment for Cincinnati has been utilized. This is a comparative index using the average for the years 1935-1939 as the standard of 100. In the table we have listed the approximate yearly index, which rose steadily from 1939 through 1943 and then began to decrease. Thus there is a roughly inverse relationship between this measure of prosperity and the number of cases of pellagra in the hospital. Presumably months or years of dietary imbalance are needed before the stigmas of pellagra reach the stage where diagnosis is obvious. Correction of the deficiency by dietary means may bring about restoration in the direction of normal more rapidly. We are of the opinion that the general improvement in the economic state of the people of Cincinnati during the late 1930's and early 1940's is the primary reason for the observed decrease in pellagra.

Since a large proportion of the cases of pellagra in this hospital are associated with alcohol addiction, a general reduction in consumption of alcoholic bever-

ages in Cincinnati might be expected to reduce the incidence of pellagra. During the period of sharp decline in incidence there was no such decrease in sales or manufacture of distilled or fermented alcoholic beverages locally.

The effect of rationing, which tended to make nutritious foods available on a per capita basis rather than on an economic one, came into operation after the abrupt fall in incidence of pellagra. It is possible that it helped perpetuate the trend.

In the table we have indicated the periods at which the program of enrichment of bread was put into practice on a voluntary basis (about 30 per cent effective locally) and on an obligatory basis (about 90 per cent effective locally).[2] Since pellagra had become relatively rare before bread was treated with vitamin supplements, this program did not initiate the change but may have served to sustain the trend of improvement. The same is true of the educational endeavors of the very active groups giving instruction in better nutrition which were not organized until American participation in World War II was in progress.

*Data on Initial Admissions for Pellagra, 1935-1947*

| Year | Medical Ward Admissions | Cases of Pellagra | Percentage | Approximate Index of Industrial Employment * | Average Weekly Wages Cincinnati* | Estimated Percentage of Bread Enriched |

* From figures supplied by the Cincinnati Chamber of Commerce.

We have no data on the per capita sales of various vitamin preparations which came into vogue in the early 1940's. It has been our experience that pills have rarely constituted a significant source of vitamins in the class of patients admitted to the hospital. It is probable that the increasing awareness of vitamin, protein and other factors on both the medical and surgical services has reduced the number of cases of secondary pellagra developing on the wards. This would have accounted for only a fraction of the decline.

### CONCLUSIONS

1. There has been a striking decrease in the number of cases of pellagra seen in the Cincinnati General Hospital in recent years.

2. Since 1940 pellagra has occurred with increasing rarity, and in the last thirty months only 1 case has been seen.

3. This change occurred during a period when active studies of the disease were in progress and interest was sustained.

4. The cause for this decrease is unknown. The most likely reason is the general improvement in the economic state of the population from which the hospital draws its patients.

5. The program of enrichment of flour and various educational activities may have served to sustain the trend but did not initiate it.

# Clinical Notes, Suggestions and New Instruments

## HYPERPYREXIA FOLLOWING THORACOLUMBAR SYMPATHECTOMY

### Report of Two Cases Occurring During a Heat Wave

JAMESON L. CHASSIN, M.D.
and
J. WILLIAM HINTON, M.D.
New York

As greater numbers of patients are subjected to thoracolumbar sympathectomy for essential hypertension, it becomes of increasing importance to learn how this operation affects the function of the organism in relation to its environment. Although it has long been known that denervation of the sympathetic nerve supply results in abolition of the sweating mechanism in the area involved, there have been to our knowledge no cases reported in which this deficiency has proved clinically deleterious to the patient.

For this reason we are reporting in detail 2 cases of hyperpyrexia which occurred during the heat wave of Aug. 25 to 30, 1948, in New York City. Both patients had almost complete absence of the sweating mechanism due to previous bilateral thoracolumbar sympathectomy done by the technic of Hinton and Lord.[1]

### REPORT OF CASES

Case 1.—A. R., a 45 year old lithographer, was admitted to the hospital for the second time on Aug. 28, 1948, complaining of heat, feverishness and some dyspnea. He noted that his symptoms had coincided with the peak of the heat wave, and he entered the hospital when his family doctor found his temperature to be 104 F.

*Past History.*—A known hypertensive patient of one and a half years' duration, the patient was first admitted to the hospital on July 28, 1948. Blood pressure was 240 systolic and 120 diastolic. The amobarbital test had lowered this to 120 systolic and 90 diastolic. Physical examination, except for hypertension, early eyeground changes and slight cardiac enlargement, had revealed no abnormalities. Laboratory examination included blood cell count, urinalysis, urine concentration test, studies of the chemical content of the blood and urea clearance. There was a faint trace of albumin. The results of other tests were within normal limits. Electrocardiographic changes were consistent with left ventricular hypertrophy.

On August 2, the patient underwent left thoracolumbar sympathectomy. All the ganglions from the second thoracic to the third lumbar, inclusive, were removed, as were the splanchnic nerves. On August 10, right thoracolumbar sympathectomy (second thoracic to third lumbar) with excision of the three splanchnic nerves was performed. The postoperative courses were not remarkable. The patient was essentially afebrile with the exception of two or three days. He was discharged on August 21, eleven days after the second operation. His resting blood pressure varied from 110 systolic and 70 diastolic to 138 systolic and 102 diastolic.

*Physical Examination.*—The blood pressure was 160 systolic and 80 diastolic, temperature 104 F., pulse rate 110 and respirations 28. The patient was well developed and nourished and appeared slightly dehydrated. He seemed to be drowsy and moderately ill. The skin was hot and dry everywhere. The lung fields were not remarkable in view of the recent operative intervention, and the results of the remainder of the examination were not contributory.

*Laboratory Observations.*—On August 28 the red blood cell count was 4,800,000, hemoglobin 13.5 Gm. and white blood cell count 7,400, with 64 per cent polymorphonuclear cells, 1 per cent eosinophils, 2 per cent basophils, 23 per cent lymphocytes and 10 per cent monocytes. A urinalysis showed a specific

gravity of 1.012, very faint trace of albumin, acid reaction and an occasional white blood cell. On August 30, the white blood cell count was 6,650, with 63 per cent polymorphonuclear cells, 1 per cent eosinophils, 29 per cent lymphocytes and 7 per cent monocytes. A roentgenogram of the chest on August 31 revealed small, localized areas of pleural thickening or fluid posteriorly and bilaterally. A small area of localized hydropneumothorax was seen on the right, at the level of the sixth rib posteriorly.

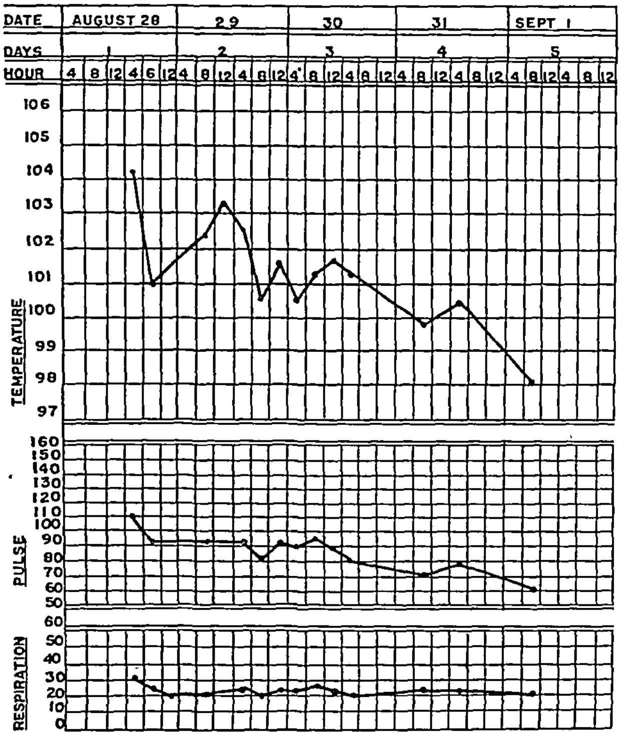

Fig. 1 (case 1).—Graphic temperature, pulse rate and respiration chart.

*Course.*—Bilateral diagnostic thoracenteses obtained only 20 cc. of old blood on the right. The patient was placed in a cold wet pack intermittently over a thirty-two hour period. On the third hospital day, his temperature remained between 100.6 and 101.6 F. The following day it fell to 99.6 to 100.4 F., and the patient became ambulatory. He was discharged on the fifth day.

Although the patient appeared somewhat drowsy on admission, his clinical appearance was not that of a dangerously ill patient. He took fluids and food fairly well. He received no chemotherapy during this period of hospitalization. At no time was perspiration noted.

*Comment.*—It is felt that this patient's hyperpyrexia was due to excessive environmental heat. The normal leukocyte count ruled against an infectious process, as did the favorable response to conservative therapy directed solely at reducing the body temperature.

Case 2.—K. M., a 53 year old housewife, was first admitted to the hospital with the complaints of nervousness and easy fatigability of seven years' duration. There was, in addition, a history of palpitations and occasional blurring of vision. One month before admission she experienced an episode of numbness in the left hand and dizziness which persisted for two to three weeks.

*Past History.*—The patient had undergone oophorectomy for "chocolate cyst" two years before admission, and she had had two normal pregnancies.

*Family History.*—The father had died of nephritis at age 45, and a brother died of a stroke at the age of 46.

*Physical Examination.*—The blood pressure was 230 systolic and 130 diastolic. Temperature, pulse rate and respirations were normal. Eyeground examination revealed some arterial narrowing and arteriovenous nicking. The heart was slightly enlarged to percussion. The results of the remainder of the physical examination were normal.

*Laboratory Observations.*—The red blood cell count was 4,170,000, hemoglobin 12.0 Gm. and white blood cell count 14,100, with 79 per cent polymorphonuclear cells. Urinalysis showed a specific gravity of 1.018; there was no albumin or sugar, and the results of other microscopic examinations were normal. The blood nonprotein nitrogen, urea nitrogen, creatinine and urea clearance were all within normal limits, as was the result of the urine concentration test. The electrocardiogram showed inversion of the T wave in lead 3, with left axis deviation considered consistent with left ventricular hypertrophy. The roentgenogram of the chest showed slight cardiac enlargement of the left ventricular type. The amobarbital sodium test lowered the blood pressure to 170 systolic and 100 diastolic.

*Course.*—On August 16, left thoracolumbar sympathectomy was performed, with complete removal of the paravertebral ganglions from the stellate ganglion (seventh cervical to first thoracic) to the third lumbar, inclusive. The greater, lesser and least splanchnic nerves were also excised. The postoperative course was essentially afebrile. On paracentesis of the left side of the chest on August 19, 21 and 23, there was obtained a total of 600 cc. of serosanguinous fluid. On August 24, right thoracolumbar sympathectomy was performed, with removal of the ganglions from the second thoracic to the third lumbar, inclusive, as well as the splanchnic nerves. A blood transfusion of 1,000 cc. was given.

On the first postoperative day, the blood pressure was maintained well, and the continuous infusion of 0.002 per cent phenylephrine hydrochloride in 10 per cent dextrose solution was stopped. The temperature rose to 102 F., and the patient became apprehensive and slightly dyspneic. Right thoracentesis at this time resulted in removal of 430 cc. of serosanguinous fluid. On the night of August 26 (second postoperative day), there was a temperature spike to 106 F. The pulse rate rose only to 104. Physical examination revealed no basis for this febrile reaction. The patient's respirations were normal. There was some perspiration over the right side of the face. Bilateral thoracenteses obtained insignificant amounts of serosanguinous fluid. This date marked the peak of the summer heat wave in New York City. It was noted that this patient's room, because of its location, was unusually hot and poorly ventilated. The patient was moved to another room and placed in a cold oxygen tent. Ice bags were applied to the extremities. The temperature promptly returned to 99 to 100 F. In addition, penicillin therapy was begun, since an infectious process could not definitely be ruled out at this time. When the oxygen tent

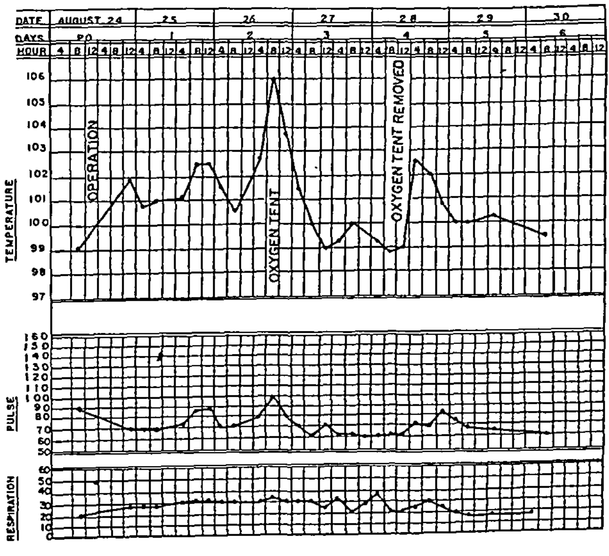

Fig. 2 (case 2).—Graphic temperature, pulse rate and respiration chart.

was removed thirty-six hours later (fourth postoperative day), the temperature again rose sharply to 102 F. However, this was easily controlled by electric fans and wet applications to the body. The patient felt well, became ambulatory and remained afebrile. Her resting blood pressure was 130 systolic and 78 diastolic. She was discharged on the eighth postoperative day with instructions to avoid intense heat.

*Comment.*—Although interpretation of this case is complicated by the recent operation, it seems clear that the acute hyperpyrexia was caused by the intense heat of the environment rather than any operative complication. The prompt response to reduction of the environmental temperature as well as the recrudescence, which followed removal of the cold oxygen tent, lend support to this view.

## COMMENT

A normal human being reacts to a hot environment in several ways: At first the cutaneous blood vessels dilate and divert a greater proportion of the circulating blood to the body surface for cooling by radiation and convection.[2] However, as the room temperature approaches and exceeds normal body temperature (98.6 F.), it becomes obvious that the body cannot dissipate its excess heat by radiation and convection alone. In the normal organism exposed to environmental temperatures above 95 F., evaporation accounts for all or almost all of the heat lost from the body.[3]

Sweat gland secretions provide most but not all of the fluid for the process of evaporation. There is also an "insensible" loss by evaporation from the skin of approximately 800 cc. a day of fluid escaping from the cutaneous capillaries by transudation.[4] Further "insensible" evaporation of water occurs in the lungs (about 400 cc. a day). The reason for our emphasizing these facts is that the sweat gland secretions are abolished by section of the sympathetic nerves to the areas involved, and, although "insensible" evaporation persists, this cannot be sufficiently increased to be of service in dissipating excessive body heat.

The usual sequence of events in cases of prolonged exposure to heat is profuse sweating, dehydration, thirst, diminished venous return, peripheral vascular collapse and syncope. This is usually termed "heat exhaustion."[5] If the patient attempts to satisfy his thirst by drinking huge draughts of water, then dehydration and hemoconcentration give way to severe hypochloremia, and the syndrome of "heat cramps" or "miner's cramps" results.[6] Neither of these syndromes is usually dangerous, and both respond fairly rapidly to rest in a cooler environment combined with saline therapy. Usually these symptoms serve as warning signals and result in removal of the patient from the hot environment before serious damage to the heat-regulating mechanism can occur. Therefore, their temperatures rarely rise above 102 F.

On the other hand, when prolonged exposure, unusual severity of heat or predisposing disease is present, hyperpyrexia or "heat stroke" may supervene. This is usually a serious condition manifested by a failure of the sweating mechanism, a temperature rise to 104 F. or higher and, in terminal cases, coma. It is in some cases preceded by symptoms of heat exhaustion, but is invariably preceded by complete cessation of sweating.[6] This syndrome is probably due to impairment of the heat-regulating centers of the central nervous system.

The 2 patients described in this report had been subjected to almost complete ablation of the sympathetic nervous system for essential hypertension. Consequently, there was almost complete elimination of the sweating mechanism. This, coupled with the elevation of the environmental temperature to a peak of 99 to 101 F. easily explains the failure of heat dissipation in these patients (table).

What is more difficult to understand is the relative infrequency of this complication in thoracolumbar sympathectomy. Although this operation has been performed on over 500 patients (by J. W. H.), only 1 instance of hyperpyrexia, in addition to the cases described herein, has come to our attention. This patient, who was in her third postoperative month, responded well at home to treatment by the family physician. It should be noted that all 3 cases of hyperpyrexia occurred relatively early in the postoperative course. There have been few long range follow-up studies of the sweating mechanism in patients subjected to sympathectomy of this type.

However, Ray and Console[7] have demonstrated that in the course of a "readjustment period" of about three months, several areas, especially in the dermatomes supplied by the twelfth thoracic to the third lumbar ganglions, show unmistakable evidence of sympathetic innervation even after total paravertebral sympathectomy. These authors produce evidence which indicates that this sympathetic activity which returns via "residual" pathways may be interrupted by anterior rhizotomy (twelfth thoracic to second lumbar). These "residual" areas of sympathetic innervation have been observed to increase slightly over a period of one to two years, and in some cases to involve both thighs and buttocks.[7] Our own clinical observations confirm the existence of these "skip" areas. They are occasionally detected even after total sympathectomy by the presence of active sweating over the anterior surface of the thighs.

The late return of the sweating mechanism following extensive (first thoracic to second lumbar) sympathectomy has been studied by Schafer[8] by means of the starch-iodine test in 1 patient who was suffering from polycythemia vera. Five months after operation some amount of sweating had returned to the skin over the anterolateral surface of both thighs. After twenty-three months sweating was noted over the entire anterior and lateral surfaces of both thighs, the suprapubic region and the radial aspect of the left forearm, as well as over a few patches of skin in the region of the left third rib anteriorly. After a thirty-nine month postoperative period, the area of sweating had extended to include both knees anteriorly, the sacroiliac region, the left scapula and a few patches over the right arm.

*Maximum Daily Temperatures in Metropolitan New York*

| Date, 1948 | Temperature, F. |
|---|---|
| August 25 | 91 |
| August 26 | 101 |
| August 27 | 99 |
| August 28 | 99 |
| August 29 | 93 |
| August 30 | 87 |
| August 31 | 79 |

From these studies,[9] it is possible to formulate an explanation for the apparently infrequent occurrence of hyperpyrexia after extensive paravertebral sympathectomy. Perhaps, once the "readjustment period" is passed, the return of the thermoregulatory sweating mechanism to these limited residual areas may be sufficient to maintain thermal homeostasis even when the temperature of the environment rises slightly above that of the body. Nevertheless, early in the postoperative period precautions should be taken to protect these patients from exposure to unusually high environmental temperatures.

## SUMMARY AND CONCLUSIONS

Two cases are reported of hyperpyrexia due to excessive environmental heat in patients who had undergone extensive thoracolumbar sympathectomy. Abolition of most of the sweating mechanism renders these patients unusually susceptible to high environmental temperatures especially during the early postoperative period.

## THE RELATIONSHIP OF TRYPTOPHANE AND NICOTINIC ACID

The name of Dr. Joseph Goldberger inevitably comes to mind in any discussion of the causation, prevention and cure of pellagra. He pioneered in the attempts to associate the appearance of the disease with causative nutritional factors; as he continued his studies he repeatedly showed the parallelism between presence or absence of pellagra and differences in the diet of the persons under examination. Particularly was the consumption of proteins of recognized superior biologic value regularly associated with the absence of the disease. In 1937 Elvehjem and his co-workers[1] demonstrated that nicotinic acid prevented and cured the canine analogue of human pellagra, and its efficacy in treating pellagra in man was promptly demonstrated.[2] The earlier suggestion that protein of high nutritional value exerted a favorable effect on human pellagra and the discovery of the curative properties of nicotinic acid were partially harmonized by the observation that, in the rat, growth is retarded if corn grits are added to an experimental diet low in nicotinic acid and that either nicotinic acid or tryptophane brings about resumption of growth.[3]

The foregoing observations suggest a more or less close relationship between protein and nicotinic acid in nutrition; indeed, hydrolyzed fibrin and gelatin both act like corn grits in retarding growth and glycine, and a mixture of amino acids simulating completely hydrolyzed casein will also have this effect.[4] The influence of corn grits in the diet has been ameliorated by use of dextrose or dextrin as a source of carbohydrate, which suggests that the metabolism of micro-organisms in the intestine may play a part in the phenomenon.[5] Using the excretion of nicotinic acid and of N-methyl nicotinamide in the urine as a criterion, Rosen and co-workers[6] showed with this criterion that the same relationship exists between tryptophane and nicotinic acid. Later it was shown that human beings behave like laboratory animals with respect to a diminished output of the metabolites of nicotinic acid when a deficiency of nicotinic acid exists and its correction with tryptophane.[7] On this basis, an amino acid imbalance produced by the administration of phenylalanine or threonine to rats gave evidence of interference with nicotinic acid–tryptophane metabolism, and the intravenous route was as effective as the oral.[8]

The rat is ordinarily able to synthesize enough nicotinic acid to maintain its physiologic well-being; however, when corn grits are added to a ration poor in nicotinic acid, the coenzyme content of liver, voluntary muscle and brain is decreased.[9] The vital part played by these enzymes in tissue oxidation suggests the gravity of the situation in which a widely used food can, through an amino acid imbalance from its protein of modest biologic value, cause this deep-seated alteration of usual physiologic chemical reactions. Further investigation of the interrelations of the known causative factors in the production of nicotinic acid deficiency is warranted by the considerable importance of the problem in the public health program.

## STREPTOMYCIN THERAPY IN PULMONARY TUBERCULOSIS

Riggins and Hinshaw[1] have summarized the results of the use of streptomycin in 332 patients with pulmonary tuberculosis; patients were treated by cooperative investigators designated by the executive committee of the American Trudeau Society. A statistical analysis was made on those who had been observed for at least ninety days after initiation of treatment. Types differing as to nature of disease, age, race and sex were treated in widely separated sections of the country. Of the 332 patients with pulmonary tuberculosis, 17 had minimal, 118 moderately advanced and 197 far advanced disease; 80 per cent had predominantly acute or subacute disease, and the remainder predominantly chronic disease at the beginning of the treatment.

The beneficial effect of streptomycin in tuberculosis, the report indicates, depends on its interference with the growth and multiplication of streptomycin-sensitive strains of Mycobacterium tuberculosis. Streptomycin apparently does not directly enhance repair to tissue, but it probably does favorably influence the tempo and quality of repair by inhibiting the growth and multiplication of tubercle bacilli. The response of the tuberculous lesion to streptomycin is apparently fundamentally related to the characteristics of the pathologic condition and the patient's ability to cope with the disease. Previous workers have demonstrated, both experimentally and clinically, that streptomycin is more effective against relatively early acute and subacute lesions, in which the extent and degree of caseation is limited, than it is against confluent and rapidly caseating and liquefying tuberculous pneumonias or against extensive chronic fibrocaseous and cavernous disease. These fundamental factors are more decisive in the degree of therapeutic effectiveness of streptomycin and the outcome of the issue than are the often overemphasized differences in total daily dosage or duration of treatment. The partial, even though temporary, control of the more active pulmonary and bronchial disease is often sufficient to permit relatively safe and effective operation. Streptomycin usually has little or no decisive therapeutic value when used alone in chronic types of cavernous disease without recent or exudative components, or in the absence of tuberculous laryngitis, tracheobronchitis or enteritis.

When it is given in relatively large daily dosage for prolonged periods, the toxic effects of streptomycin prove to be second only in importance to the emergence of drug-fast organisms as a limiting factor in the usefulness of the drug. When streptomycin was administered intramuscularly in 2 to 3 Gm. daily doses, disturbing and often severe toxic manifestations were frequent, the most serious being deafness and loss of labyrinthine function. Serious toxic manifestations can be largely avoided if attention is paid to the selection of the proper dosage schedule, which is best calculated on a milligram per kilogram of body weight basis. Toxic effects of any consequence are rarely encountered in patients receiving daily dosage of 20 mg. per kilogram of body weight. A daily dosage of 30 to 40 mg. per kilogram of body weight exerts a greater therapeutic effect, at least in certain types of disease. It was hoped that dihydrostreptomycin would be of lower toxicity than streptomycin, but recent data indicate that this may not be the case. Further investigation of this derivative is necessary before widespread use can be recommended.

Although improvement occurred much more frequently and was more definite in patients with predominantly acute disease than in those with the predominantly chronic disease, significant improvement was reported by most of the investigators in a small percentage of patients with chronic disease. As the progression of chronic tuberculosis is fundamentally related to the occurrence of acute episodes, the great potentialities of the strategic use of short courses of streptomycin to combat such episodes should be stressed. The occurrence of drug-fast organisms was definitely related to duration of treatment. Organisms resistant to 10 or more micrograms of streptomycin per cubic centimeter rarely occurred in patients treated for one month, but appeared frequently in patients treated for two months or more. Drug fastness is a significant factor in limiting the effectiveness of the antibiotic. The failure to close cavities and convert sputum in a large percentage of patients and the relapse of the disease with increasing frequency with passage of time suggest the limitations of antibacterial therapy in this disease. Collapse therapy is absolutely necessary in some cases for achieving lasting results.

## DERMATOME PATTERNS IN THE EXTREMITIES

J. J. Keegan and F. D. Garrett[1] have recently reported new and highly significant information on segmental distribution of cutaneous nerves in the extremities. New patterns were derived by study of single nerve compressions in herniations of intervertebral disks. In this study 165 cases of hypalgesia of the upper limb and 1,264 cases of hypalgesia of the lower limb are described. Forty-seven of the lesions in the upper extremity and 707 of those in the lower were verified by surgery. Previous original studies by Keegan[2] are reported, and comparisons are made with dermatome charts developed by Sherrington, Bolk, Head and Foerster. The new charts differ significantly from those constructed by previous investigators in that a regular pattern of serial dermatomes in the limbs extending as continuous patterns from the dorsal midline of the body down the arms and legs are described. Nerve distribution patterns of the second, third, fourth and fifth cervical nerves, the first thoracic, the second, third, fourth and fifth lumbar and the first, second and third sacral are described in detail. Areas were mapped by determination of pain hypalgesia to pin prick and pin scratch. Heat and cold sensation areas were not mapped, as it was believed that finer demarcation and less apparent overlapping occurred in pain sensation. Sherrington's results were obtained by isolating single nerve roots in the Macacus rhesus monkey; Bolk's data were determined by careful gross dissection of a single human body; Head's data were largely drawn from the distribution of skin lesions from herpes zoster involving a single nerve root, and Foerster's data were obtained, as with Sherrington, by

Neurosurg. **4**: 115-139, 1947; Diagnosis of Herniation of Lumbar Intervertebral Disks by Neurologic Signs, J. A. M. A. **126**: 868-873 (Dec. 2) 1944; Neurosurgical Interpretation of Dermatome Hypalgesia with Herniation of the Lumbar Intervertebral Disc, J. Bone & Joint Surg. **26**: 238-248 (April) 1944; Dermatome Hypalgesia Associated with Herniation of Intervertebral Disk, Arch. Neurol. & Psychiat. **50**: 67-83 (July) 1943.

isolation of a single nerve root plus faradic stimulation of the root and the plotting of resultant areas of vasodilatation.

The newly defined dermatome areas of hyposensitivity are interpreted as primitive dermatomes. The study demonstrates that the amount of overlap in single nerve sensation patterns is much less than previously believed. Foerster had stated previously that the amount of overlap of single nerve dermatomes was so considerable that division of a single nerve root did not produce loss of sensibility. Additionally, the study indicated that postulation of a loop configuration of the dermatomes, as suggested by Sherrington, are probably untenable. New information provided by these studies offers considerable aid to accurate diagnoses of single nerve root lesions of the cervical and lumbar portions of the spine.

A subjective mechanism of study, dependent on pain cognition in persons with known variability in pain thresholds, was used throughout. Nevertheless, results of the study have apparently clarified much previous confusion regarding sensory nerve distribution of the extremities.

## Current Comment

### CONTROL OF MURINE TYPHUS WITH DDT

In the United States, murine typhus, according to Assistant Surgeon General C. L. Williams,[1] constitutes an important problem in nine states grouped in the Southeast. These states are: North Carolina, South Carolina, Georgia, Florida, Tennessee, Alabama, Mississippi, Louisiana and Texas. Ninety-two per cent of the human cases of murine typhus in the United States are reported in these nine states. Despite the rat destruction and rat-proofing programs a steady rapid increase has taken place, moving from 1,882 cases in 1940 to 5,401 in 1944. In 1944, personnel of the United States Public Health Service carried out experiments on the control of rodent ectoparasites, using DDT mixed with an inert powder to dust rat runs in buildings. Results indicated that flea indexes in buildings could be reduced by as much as 90 per cent and could be kept at a low level for about three months. A flea control project was begun in 1945, federal funds for that purpose being made available. The program was carried on by state health departments according to a uniform pattern established in agreement with the Public Health Service. As the result of this campaign there was a progressive reduction in the incidence of the disease. In 1944 there were 5,401 cases of murine typhus reported in the United States. In 1945 there were 5,193, in 1946 there were 3,365 and in 1947 the number was 2,034, which represents an over-all decline of about 62 per cent. The steady decline has continued into 1948, present data indicating that there will be reported between 1,100 and 1,200 cases. The material used is a dust mixture of 10 per cent DDT to 90 per cent pyrophyllite. This dust is spread along rat runs, in burrows and, so far as practicable, into rat harborages. The theory of operation is not to dust the rats themselves but to kill the fleas when they drop off the rats. Apparently rats carry the dust in which they have walked to their nests where additional fleas are killed. Through this method, two main types of rat fleas (X. cheopis and L. segnis) have been greatly reduced in numbers. In addition to the reduction in rat fleas, incidence in rats of a positive complement fixation reaction for typhus also decreased. The author believes that DDT dusting is superior to any other method now in use for the rapid control of any disease carried solely or principally by rat fleas.

### ALTERATION THERAPY IN PULMONARY TUBERCULOSIS

The Japanese investigators Susumu Nukada and Chieko Ryu[1] report interesting animal experiments in tuberculosis using heterospecific vaccines. Vaccines made from bacteria including gonococci, dysentery bacilli, streptococci and typhoid bacilli were given to rabbits and guinea pigs with experimental tuberculous infection. Vaccination was also performed prior to the induction of experimental tuberculosis. Control animals were observed and compared in each instance. Control vaccine made from Eberthella typhosa and Neisseria gonorrhoeae and the mixed autolysate of these bacteria protected animals from a rapid advance of preexisting or subsequently induced tuberculosis. A mixed autolysate was prepared by separately suspending each strain of bacteria in sterile distilled water, killing by heating to 53 C. for one hour, and incubation for ten days followed by centrifugation at 10,000 revolutions per minute. The clear autolysate obtained was rendered isotonic with sodium chloride, and carbolic acid added. Autolysates of E. typhosa and N. gonorrhoeae were mixed in the proportion of 1 to 3. Vaccination with a mixture of typhoid and gonococcus vaccine increased resistance against tuberculous infection of both guinea pigs and rabbits. These treated animals showed significant increase of life span as compared with untreated control animals. Average survival time of tuberculous animals vaccinated with the autolysate was 23.2 days, and life span of those inoculated with the vaccine, 19 days. Control animals died in an average of 14.4 days. Nine hundred and thirty-two patients with pulmonary tuberculosis were then treated with the mixed autolysate during the five year period (1940 to 1945). Of 703 patients with incipient and mild forms of tuberculosis, 550 were stated to have recovered completely and 151 were improved. Of 229 moderately and severely ill patients, 107 improved and 72 recovered. The treatment results observed are described as being due to a "heterospecific increase of resistance." The methods and results reported are interesting. However, the excellent results now obtained with streptomycin therapy far overshadow vaccine treatment reported, especially in advanced stages of human tuberculosis.

# ORGANIZATION SECTION

# PROCEEDINGS of the ATLANTIC CITY SESSION

## MINUTES OF THE SCIENTIFIC SECTIONS

### SECTION ON INTERNAL MEDICINE

WEDNESDAY MORNING, JUNE 8, 1949

The meeting was called to order at 9:05 a. m. by the chairman, Dr. M. A. Blankenhorn, Cincinnati.

The first paper, "The Diagnostic Value of Cardiac Auscultation," by Dr. Samuel A. Levine of Boston, was discussed by Dr. Howard B. Sprague of Boston.

"Neurocirculatory Asthenia (Anxiety Neurosis, Effort Syndrome): A Twenty-Year Follow-Up Study of 173 Patients," by Drs. E. O. Wheeler, P. D. White, E. W. Reed and M. E. Cohen of Boston, was read by Dr. Wheeler and discussed by Drs. Arthur M. Master, New York; Hobart A. Reimann, Philadelphia, and Weldon J. Walker, Canal Zone, and Dr. Wheeler.

"The Role of Coronary Vasodilating Drugs in Coronary Occlusion," by Drs. N. C. Gilbert, G. K. Fenn and L. A. Nalefski, Chicago, was presented by Dr. Nalefski and discussed by Drs. Roy W. Scott, Cleveland, and W. M. Fowler, Iowa City, and Dr. Nalefski.

"The Frank Billings Lecture: Osler and the American Medical Association," was presented by Dr. Reginald Fitz of Boston.

"Bacteremia Following Tooth Extraction: Prevention With Penicillin and a New Solfonamide, Gantrosan," by Drs. Paul S. Rhoads and Warren R. Schram, Chicago, was read by Dr. Rhoads and discussed by Drs. Robert J. Glaser, St. Louis, and Harry F. Dowling, Washington, D. C., and Dr. Rhoads.

"Diagnostic Problems of Prolonged Fever," by Dr. Hobart A. Reimann, Philadelphia, was discussed by Drs. Wesley W. Spink, Minneapolis, and Harold Jeghers, Washington, D. C.

THURSDAY, JUNE 9—MORNING

Election of officers was held, with the following results: chairman, Arthur Bloomfield, San Francisco; vice chairman, Ralph Kinsella, St. Louis; secretary, W. L. Palmer, Chicago; representative to House of Delegates, C. T. Stone, Galeston, Texas; alternate, W. D. Stroud, Philadelphia; executive committee, Cecil J. Watson, Minneapolis; M. A. Blankenhorn, Cincinnati, and Arthur Bloomfield, San Francisco.

"Critique of Reports of the Surgical and Dietary Therapy in Hypertension," by Dr. David Ayman, Boston, was discussed by Drs. Frederick M. Allen, New York, and Keith S. Grimson, Durham, N. C., and Dr. Ayman.

"Hazards in the Use of Low Salt Diets," by Dr. Henry A. Schroeder, St. Louis, was discussed by Dr. J. Edwin Wood Jr., Charlottesville, Va., and Dr. Schroeder.

"Deficiency Diseases in a General Hospital; A Ten-Year Study," the chairman's address, was presented by Dr. M. A. Blankenhorn, Cincinnati.

"The Prepsychotic and Early Psychotic Sees the Family Doctor or Internist First," by Drs. G. Gill Richards and Louis G. Moench, Salt Lake City, was read by Dr. Moench and discussed by Dr. Herbert F. Robb, Belleville, Mich., with closing discussion by Dr. Moench.

"Other Factors Besides Allergy in Asthma," by Dr. Francis M. Rackemann, Boston, was discussed by Drs. Simon S. Leopold, Philadelphia, and George Piness, Los Angeles, and Dr. Rackemann.

"The Use of Radioactive Isotopes in Clinical Medicine," by Dr. John Z. Bowers, Washington, D. C., was discussed by Dr. Paul C. Aebersold, Oak Ridge, Tenn., with closing discussion by Dr. Bowers.

*Joint Session*

FRIDAY, JUNE 10—MORNING

"The General Management of Rheumatoid Arthritis," by Dr. Charles A. Ragan of New York, was discussed by Dr. Hans Waine, Winchester, Mass., and Dr. Ragan.

"The Present Status of Gold Therapy in Rheumatoid Arthritis," by Dr. Richard H. Freyberg, New York, was discussed by Dr. Leslie J. A. Parr, Sydney, Australia, and Dr. Freyberg.

"Prevention and Treatment of Deformities in Rheumatoid Arthritis," by Drs. Donald F. Hill and W. Paul Holbrook, Tucson, Ariz., was discussed by Dr. Robert L. Preston, New York, and Dr. Donald F. Hill.

Dr. Dwight L. Wilbur, chairman of the Section on Experimental Medicine and Therapeutics, which was holding a joint session with the Section on Internal Medicine, assumed the chair for the balance of the session.

"NPH-50 (Modified Protamine) Insulin in the Treatment of Severe Diabetes," was read by Dr. Priscilla White of Boston and discussed by Dr. Cyril M. MacBryde, St. Louis, and Dr. Henry T. Ricketts, Chicago, with closing discussion by Dr. White.

"Treatment of Myasthenia Gravis," by Drs. Charles T. Stone and J. Alfred Rider of Galveston, Texas, was presented by Dr. Stone and discussed by Dr. David Grobe, Baltimore, and Dr. Stone.

"Favorable Results in Bulbar Poliomyelitis Treated as a Problem in Respiratory Obstruction," by Drs. Thomas C. Galloway, Evanston, Ill., and Martin H. Seifert, Wilmette, Ill., was read by Dr. Galloway and discussed by Drs. Albert G. Bowers, Pasadena, Calif.; F. R. Kleaner, Reidville, N. C.; Joseph R. Brown, Minneapolis; Allen Conroy, Chicago, and George J. Boines, Wilmington, Del.; closing discussion by Dr. Seifert.

### SECTION ON SURGERY, GENERAL AND ABDOMINAL

WEDNESDAY, JUNE 8—AFTERNOON

The meeting was called to order at 2:05 p. m. by the chairman, Dr. William F. MacFee, New York.

Dr. Claude E. Welch, Boston, read a paper on "Acute Massive Hemorrhage from the Upper Gastrointestinal Tract." Discussed by Drs. John Stewart, Buffalo; Jonathan E. Rhoads, Philadelphia; Otto DeMuth, Vancouver, British Columbia, and Claude E. Welch, Boston.

Dr. Howard K. Gray, Rochester, Minn., read a paper on "Results of Classical Operations for Duodenal Ulcer and Benign Ulcerating Lesions of the Stomach." Discussed by Drs. I. Ridgeway Trimble, Baltimore; Harold D. Harvey, New York; Otto DeMuth, Vancouver, British Columbia, and Howard K. Gray, Rochester, Minn.

Dr. D. Henry Poer, Atlanta, Ga., read a paper on "Changing Concepts in the Use of Colostomy." Discussed by Drs. Claude E. Welch, Boston; Fred W. Rankin, Lexington, Ky., and D. Henry Poer, Atlanta.

Drs. Vinton E. Siler and John H. Wulsin, Cincinnati, presented a paper on "Acute Pancreatitis." Discussed by Drs. Alton Ochsner, New Orleans; Robert Elman, St. Louis, and Vinton E. Siler, Cincinnati.

Major Edwin J. Pulaski, Lieut. James F. Connell and Col. Sam F. Seeley, Medical Corps, United States Army, presented a paper on "Sterilization of the Intestinal Tract by Antibiotics and Supplemental Agents." Discussed by Drs. John S. Lockwood, New York; Edgar J. Poth, Galveston, Texas, and Major Edwin J. Pulaski, Medical Corps, United States Army.

Dr. Amos R. Koontz, Baltimore, read a paper on "Some Common Fallacies and Confusions with Regard to Inguinal Hernia Repair." Discussed by Drs. Guy W. Horsley, Richmond, Va.; Bradley L. Coley, New York; Leigh F. Watson, Los Angeles; Roland I. Grausman, New York, and Amos R. Koontz, Baltimore.

### Thursday, June 9—Afternoon

The following officers were elected: chairman, Dr. Michael DeBakey, Houston; vice chairman, Dr. R. Glen Spurling, Louisville, and secretary, Dr. Ridgeway Trimble, Baltimore.

Dr. William F. MacFee, New York, read the chairman's address, entitled "Painless Jaundice."

Drs. R. Glen Spurling and Ludwig H. Segerberg, Louisville, Ky., presented a paper on "Craniocerebral Trauma." Discussed by Dr. Barnes Woodhall, Durham, N. C.

Dr. Geza de Takats, Chicago, read a paper on "The Present Status of Anticoagulant Therapy in Surgery." Discussed by Drs. Alton Ochsner, New Orleans; Walter F. Kvale, Rochester, Minn.; Norman E. Freeman, San Francisco; Sylvan Moolten, New Brunswick, N. J., and Geza de Takats, Chicago.

Dr. Carl A. Moyer, Dallas, read a paper on "Acute Changes in Renal Function Associated with Major Surgical Procedures." Discussed by Drs. Ernest E. Muirhead, Dallas; Otto DeMuth, Vancouver, British Columbia; Edward McLaughlin, Philadelphia, and Carl A. Moyer, Dallas.

Dr. Francis D. Moore, Boston, read a paper on "Adaptation of Supportive Therapy to the Needs of the Surgical Patient." Discussed by Drs. Carl A. Moyer, Dallas, and Francis D. Moore, Boston.

### Friday, June 10

The Section met jointly with the Section on Anesthesiology.

## SECTION ON OBSTETRICS AND GYNECOLOGY

### Wednesday, June 8—Morning

The meeting was called to order at 9:10 a. m. by the chairman, Dr. Leroy A. Calkins, Kansas City, Kan.

A resolution was adopted endorsing the Congress of Obstetrics and Gynecology to be held in New York, May 14-19, 1950, and urging support by individual members becoming members of the American Committee on Maternal Welfare.

Dr. Joseph J. Bunim, New York, read a paper on "Rheumatic Heart Disease in Pregnancy." Discussed by Drs. Julius Jensen, St. Louis; Burton E. Hamilton, Boston; Nicholson J. Eastman, Baltimore, and Joseph J. Bunim, New York.

Dr. Duncan E. Reid, Boston, read a paper on "Evaluation of Present Day Trends Pertaining to Personality and Psychologic Aspects of Pregnancy." Discussed by Drs. Sprague H. Gardiner, Indianapolis; Gordon R. Kamman, St. Paul, and Duncan E. Reid, Boston.

Drs. John R. McCain and Samuel R. Poliakoff, Atlanta, Ga., presented a paper on "The Conservative Treatment of Premature Separation of the Normally Implanted Placenta." Discussed by Drs. M. Pierce Rucker, Richmond, Va.; C. O. McCormick, Indianapolis; Edward G. Waters, Jersey City, N. J.; J. P. Greenhill, Chicago, and John R. McCain, Atlanta.

Drs. Lois A. Day and Philip L. Smith, Rochester, Minn., presented a paper on "The Reproductive Careers of Women Who Have Menstrual Dysfunctions." Discussed by Drs. Jean Paul Pratt, Detroit; S. Leon Israel, Philadelphia, and Lois A. Day, Rochester, Minn.

Dr. G. E. Seegar Jones, Baltimore, read a paper on "Newer Methods in the Management of Infertility." Discussed by Drs. J. P. Greenhill, Chicago; John Rock, Brookline, Mass.; Sophia Kleegman, New York; Abraham E. Rakoff, Philadelphia; Karl Karnaky, Houston, Texas, and G. E. Seegar Jones, Baltimore.

Drs. M. Edward Davis and Nicholas W. Fugo, presented a paper on "Steroid Therapy in Early Pregnancy Complications." Discussed by Drs. Olive W. Smith, Brookline, Mass.; A. E. Rakoff, Philadelphia; A. R. Abarbanel, Los Angeles; Karl Karnaky, Houston, Texas, and M. Edward Davis, Chicago.

### Thursday, June 9—Morning

The following officers were elected: chairman, Dr. James R. Bloss, Huntington, W. Va.; vice chairman, Dr. Bernard J. Hanley, Los Angeles; secretary, Dr. Arthur B. Hunt, Rochester, Minn.; delegate, Dr. Harvey B. Matthews, Brooklyn, N. Y.; alternate, Dr. Daniel Morton, San Francisco; member of Board of Governors of American College of Surgeons, Dr. Emil Novak, Baltimore; members of American Committee on Maternal Welfare, Drs. Benbrow Thompson, Los Angeles; Robert D. Mussey Sr., Rochester, Minn., and Oren Moore, Charlotte, N. C.; representative to Scientific Committee to American Medical Association, Dr. F. H. Falls, Chicago; representative to National Federation of Obstetrics-Gynecological Societies, Dr. Ralph E. Campbell, Madison, Wis.

Dr. Leroy A. Calkins, Kansas City, Kan., read the chairman's address, entitled "Reproduction in the Older Woman."

Dr. H. Robert Berman, Newark, N. J., read a paper on "A New Simplified Classification of the Pelvis." Discussed by Drs. Paul C. Swenson, Philadelphia, and H. Robert Berman, Newark, N. J.

Dr. Paula Marie Horn, Los Angeles, read a paper on "Pregnancy Complicated by Anterior Poliomyelitis." Discussed by Drs. Leon S. McGoogan, Omaha; A. G. Bower, Pasadena, Calif.; Harry M. Kirschbaum, Detroit; Frederick H. Falls, Chicago, and Paula Marie Horn, Los Angeles.

Drs. Clifford B. Lull and Robert M. Mitchell, Philadelphia, presented a paper on "The Pomeroy Operation for Sterilization." Discussed by Drs. William F. Nelms, Brooklyn; G. Wilson Hunter, Fargo, N. D., and Clifford B. Lull, Philadelphia.

Drs. E. Stewart Taylor, James R. Phalen and Harold L. Dyer, Denver, presented a paper on "The Effect of Obstetric Difficulties and Maternal Diseases on Premature Mortality."

Drs. William H. Masters and Robert W. Ross, St. Louis, presented a paper on "The Protection of Premature Infants Provided by the Various Methods of Conduction Anesthesia."

The two aforementioned papers were discussed by Drs. Franklin F. Snyder, Cambridge, Mass.; James K. Quigley, Rochester, N. Y.; Robert A. Hingson, Baltimore; Harry M. Kirschbaum, Detroit; Carl H. Tafeen, Brooklyn; E. Stewart Taylor, Denver, and William H. Masters, St. Louis.

### Friday, June 10—Morning

Drs. William C. Keettel and Everett D. Plass, Iowa City, presented a paper on "A Study of Prophylactic Penicillin Administration to Obstetric Patients." Discussed by Drs. E. Stewart Taylor, Denver; Louis H. Douglass, Baltimore, and William C. Keettel, Iowa City.

Drs. Roy W. Mohler and George A. Hahn, Philadelphia, presented a paper on "The Normal Cervix Uteri and Its Clinical Significance." Discussed by Drs. Wesley T. Pommerenke, Rochester, N. Y., and Roy W. Mohler, Philadelphia.

Drs. H. E. Nieburgs and Edgar R. Pund, Augusta, Ga., presented a paper on "Evaluation of Comparative Exfoliative Cytology for the Detection of Cancer of the Cervix Uteri." Discussed by Drs. Willis E. Brown, Iowa City; Emil Novak, Baltimore, and Martin W. Diethelm, Toledo.

Drs. Lester D. Odell and James C. Burt, Chicago, presented a paper on "A New Diagnostic Adjunct for Uterine Cancer." Discussed by J. Thorton Wallace, Brooklyn; M. Edward Davis, Chicago; James Burt, Chicago, and Herbert E. Schmitz, Chicago.

Drs. Eleanor S. Percival and A. D. Campbell, Montreal, Quebec, Canada, presented a paper on "The Status of Radium Therapy in the Carcinoma of the Cervix." Discussed by Drs. Howard C. Taylor Jr., New York; Herbert E. Schmitz, Chicago; Harry M. Kirschbaum, Detroit, and Eleanor S. Percival, Montreal.

Dr. John C. Hirst, Philadelphia, read a paper on "Carcinoma of the Cervix Complicating Pregnancy." Discussed by Drs. W. O. Johnson, Louisville; Joseph Kelso, Oklahoma City, and John C. Hirst, Philadelphia.

The symposium was followed by a question and answer period.

The meeting adjourned at 12:40 p. m.

## SECTION ON OPHTHALMOLOGY

### WEDNESDAY, JUNE 8—AFTERNOON

The meeting was called to order at 2 p. m. by the chairman, Dr. M. Hayward Post, St. Louis.

Dr. M. Hayward Post, St. Louis, read the chairman's address, entitled "The Function of the Eye Section of the American Medical Association."

Col. William Stone, Washington, D. C., in introducing a symposium on ocular injuries, presented a paper on "Eye Injuries in the Armed Forces."

Dr. W. Morton Grant, Boston, read a paper on "Chemical Burns of the Eye."

Dr. David G. Cogan, Boston, presented a paper on "Lesions of the Eye from Radiant Energy."

Dr. Brittain F. Payne, New York, read a paper on "Ocular Contusions in National Emergencies."

Dr. Don Marshall, Kalamazoo, Mich., presented a paper on "Lacerations and Perforations."

Dr. Alston Callahan, Birmingham, Ala., read a paper on "Intraocular Foreign Bodies."

Dr. Derrick Vail, Chicago, presented a summary of the symposium.

A question and answer period followed.

The paper on "Lacerations and Perforations," by Dr. Don Marshall, Kalamazoo, Mich., was discussed by Drs. I. S. Tassman, Philadelphia, and Don Marshall, Kalamazoo, Mich.

The paper on "Intraocular Foreign Bodies," by Dr. Alston Callahan, Birmingham, Ala., was discussed by Drs. J. S. Shipman, Philadelphia, and Alston Callahan, Birmingham, Ala.

A question submitted by Dr. Aryeh Feigenbaum, Jerusalem, was answered by Dr. Derrick Vail, Chicago.

### THURSDAY, JUNE 9—AFTERNOON

Dr. Conrad Berens, New York, was awarded the medal of the Section, the presentation being made by the chairman, Dr. M. Hayward Post, St. Louis.

Dr. Derrick Vail, Chicago, delivered to the chairman a gavel block, presented as a gift to the Section by Mrs. John E. Weeks.

On motion of Dr. Derrick Vail, Chicago, seconded by Dr. Arthur J. Bedell, Albany, N. Y., a rising vote of thanks was extended to Mrs. Weeks.

Dr. William L. Benedict, Rochester, Minn., presented the report of the Advisory Committee to the Eye Health Committee of the Student Health Association, which was accepted on motion of Dr. Arthur J. Bedell, Albany, N. Y.

Dr. William L. Benedict, Rochester, Minn., gave his report as the Section's delegate to the House of Delegates, which was accepted.

Dr. Thomas D. Allen, Chicago, reported for the American Committee on Optics and Visual Physiology. It was voted, on motion of Dr. Arthur J. Bedell, Albany, N. Y., seconded by Dr. Conrad Berens, New York, that the report be accepted and that the committee be thanked and continued.

Dr. Burton Chance reported that the Committee for Award of Knapp Medal for 1947 deemed none of the 1947 papers worthy of the award. This report was accepted.

Dr. Arnold Knapp, New York, submitted his report for the Committee for Award of Knapp Medal for 1948, and also recommended that no award be made. On motion of Dr. Conrad Berens, New York, it was voted that the report be accepted.

In the absence of Dr. John H. Dunnington, New York, his report for the Committee on American Board of Ophthalmology was read by the secretary. On motion of Dr. Conrad Berens, New York, it was accepted.

The chairman read Dr. Jonas S. Friedenwald's report for the Committee on National Museum of Ophthalmic Pathology. On motion of Dr. Conrad Berens, New York, it was accepted.

The report of the Committee on Museum of Ophthalmic History was given by Dr. Burton Chance, and on motion of Dr. Conrad Berens, New York, it was accepted.

Dr. Lawrence T. Post, St. Louis, gave the report of the Committee on American Orthoptic Council. On motion of Dr. Conrad Berens, New York, this report and the recommendations contained therein were accepted.

Dr. J. N. Greear, Washington, D. C., gave the report of Representatives from the Section to the Board of Governors of the American College of Surgeons, which was accepted.

In the absence of Dr. Albert D. Ruedemann, his report on Representatives from the Section to the Joint Committee of Industrial Ophthalmology was read by Dr. M. Hayward Post, St. Louis. On motion of Dr. Conrad Berens, it was voted to accept the report.

The report of the Knapp Testimonial Fund was given by Dr. Parker Heath, Boston. On motion of Dr. Lawrence T. Post, St. Louis, the report was accepted.

Dr. Derrick Vail, Chicago, reported for the Committee on Public Relations and stated that the committee wished to be discontinued. On motion of Dr. Arthur J. Bedell, Albany, N. Y., seconded by Dr. Conrad Berens, New York, it was voted to accept the report and discharge the committee.

Dr. Trygve Gundersen, Boston, read the report on the Howe Fund. On motion of Dr. Conrad Berens, New York, it was voted to accept the report.

Dr. Conrad Berens, New York, gave the report of the Committee on Nomenclature. On motion of Dr. Lawrence T. Post, St. Louis, this report was accepted.

Dr. Georgiana D. Theobald, Oak Park, Ill., presented the report of the Committee on Scientific Exhibit, which was accepted.

Dr. Derrick Vail, Chicago, presented the report of the Executive Committee. After reading the section of the report dealing with the recommendation on the reactivation of *Fall Bulletin* and *Presessional Bulletin*, he moved the adoption of that section of the report. The motion was seconded by Dr. Conrad Berens, New York, was put to a vote and was carried.

Dr. Derrick Vail, after having read the following section of the report, moved its adoption:

"2. Restatement of Establishment and Purposes of Knapp Testimonial Fund: The Executive Committee of the Section has investigated the establishment of the Herman Knapp Testimonial Fund and wishes to bring up to date and to have spread on the minutes of the Section, a statement of the purposes for which it was originally established in 1910 and modified in 1912.

(*a*) A Knapp Medal to contributors who are members of the Section for original work in ophthalmology or a summary of the literature, or some contribution of such a highly meritorious character in the field of ophthalmology as would warrant the granting of a medal."

After the motion of Dr. Vail had been seconded, Dr. Arthur J. Bedell, Albany, N. Y., offered an amendment that the whole matter of the restatement of establishment and purposes of the Knapp Testimonial Fund be referred back to the Committee for Award of the Knapp Medal and the Executive Committee, and be brought before the Section next year. The amendment, having been seconded and discussed, was put to a vote and was carried.

The motion as amended was carried.

After having read the following portion of the report, Dr. Vail moved its adoption:

"3. Renaming of Ophthalmic Research Medal: The Executive Committee of the Section recommends that the name of the medal of the Section hitherto known as the 'Ophthalmic Research Medal, Section on Ophthalmology, American Medical Association,' be changed to 'Medal for Outstanding Contributions to Ophthalmology.'"

The motion was seconded by Dr. Arthur J. Bedell, Albany, N. Y., was put to a vote and was carried.

The following committee appointments were approved: Committee to represent the Section on Ophthalmology at the Helmholtz Centennial in 1950, Dr. Michael J. Hogan, San Francisco, and Dr. Orwyn H. Ellis, Los Angeles; Joint Committee on Optics and Visual Physiology, Dr. Walter B. Lancaster, Boston; Committee on American Board of Ophthalmology, Dr. John H. Dunnington, New York; chairman, Section Committee on Scientific Exhibit, Dr. Donald J. Lyle, Cincinnati; Committee on American Orthoptic Council, Dr. LeGrand Hardy, New York; representative to Board of Governors of American College of Surgeons, Dr. Albert D. Ruedemann, Detroit.

The following officers were elected: chairman, Dr. A. Ray Irvine, Beverly Hills, Calif.; vice chairman, Dr. Albert N. Lemoine, Kansas City, Mo.; secretary, Dr. Trygve Gundersen, Boston; executive committee: Dr. Everett L. Goar, Houston, Texas; Dr. M. Hayward Post, St. Louis; Dr. A. Ray Irvine, Beverly Hills, Calif.; delegate, William L. Benedict, Rochester, Minn.; alternate, Dr. Parker Heath, Boston.

The following committee for the Knapp Medal award was elected: Dr. Arnold Knapp, New York; Dr. Francis H. Adler, Philadelphia; Dr. P. J. Leinfelder, Iowa City.

Dr. Merrill J. King, Boston, read a paper on "A Clinical Study of 238 Cases of Retrolental Fibroplasia." Discussed by Drs. William C. Owens, Baltimore; Arthur C. Unsworth, Hartford, Conn., and Merrill J. King, Boston.

Dr. Parker Heath, Boston, presented a paper on "Retrolental Fibroplasia: A Study of Its Pathology." Discussed by Drs. Algernon B. Reese, New York, and Parker Heath, Boston.

Drs. James H. Allen and Luciano Barrere, Iowa City, presented a paper on "Prophylaxis of Gonorrheal Ophthalmia of the Newborn." Discussed by Drs. Alan C. Woods, Baltimore; Jay G. Linn, Pittsburgh; Louis Lehrfeld, Philadelphia, and James H. Allen, Iowa City.

Drs. Alfred Cowan and Joseph V. Klauder, Philadelphia, presented a paper on "The Frequency of the Occurrence of Cataract in Atopic Dermatitis." Discussed by Drs. William P. Beetham, Boston; Arthur Alexander Knapp, New York, and Alfred Cowan, Philadelphia.

New instruments were demonstrated by Drs. Walter B. Lancaster, Boston; Thomas D. Allen, Chicago; Conrad Berens, New York; James E. Lebensohn, Chicago; William H. Luedde, St. Louis, and Harvey Thorpe, Pittsburgh.

### Friday, June 10—Afternoon

Dr. Gambiattista Bietti, Pavia, Italy, read a paper on "New Trends in Ciliary Body Surgery for the Relief of Glaucoma." Discussed by Drs. Conrad Berens, New York; S. J. Meyer, Chicago; Lawrence T. Post, St. Louis, and Gambiattista Bietti, Pavia, Italy.

Dr. Paul W. Miles, St. Louis, read a paper on "Flicker Fusion Fields: III. Findings in Early Glaucoma." Discussed by Drs. Lawrence T. Post and Paul W. Miles, St. Louis.

Drs. R. Douglas Sanders and Norman L. Cutler, Wilmington, Del., presented a paper on "General Anesthesia for Cataract Surgery."

Dr. Felician J. Slataper, Houston, Texas, read a paper on "Age Norms of Refraction and Vision." Discussed by Drs. Alfred Cowan, Philadelphia; Everett L. Goar, Houston, Texas, and Filician J. Slataper, Houston, Texas.

Dr. J. Rudolph Jaeger, Philadelphia, read a paper on "The Syndrome of Aneurysm of the Intracranial Carotid: Frontal Headache with Oculomotor Nerve Paralysis." Discussed by Drs. Frank E. Walsh, Baltimore; James W. Smith, New York, and J. Rudolph Jaeger, Philadelphia.

Dr. David B. Kirby, New York, read a paper on "The Use of Curare in Intraocular Surgery." Discussed by Drs. Frederick C. Cordes, San Francisco; W. B. Clark, New Orleans, and David B. Kirby, New York.

## SECTION ON LARYNGOLOGY, OTOLOGY AND RHINOLOGY

### Wednesday, June 8—Morning

The meeting was called to order at 9:10 a. m. by the chairman, Dr. Henry B. Orton, Newark, N. J.

Dr. Daniel S. Cunning, New York, presented a paper on "Diagnosis and Treatment of Laryngeal Tumors." Discussed by Drs. Morley T. Smith, New Rochelle, N. Y.; Edward J. Whalen, Hartford, Conn.; Joseph I. Kemler, Baltimore; Henry M. Scheer, New York; Maurice Lenz, New York, and Daniel S. Cunning, New York.

Dr. Stacy R. Guild, Baltimore, read a paper on "Interpretation of Hearing Tests, with Special Reference to Conduction Deafness." Discussed by Drs. Thomas Sage, Detroit; James B. Costen, St. Louis; Arthur L. Juers, Chicago, and Stacy R. Guild, Baltimore.

Dr. Lyndon A. Peer, Newark, N. J., presented a paper on "Complete Reconstruction of the Auricle with Diced Cartilage Grafts Inserted in a Perforated Vitallium® Ear Mold." Discussed by Drs. Clarence Straatsma, New York; Frederick A. Figi, Rochester, Minn., and Lyndon A. Peer, Newark, N. J.

Dr. Walter P. Work, San Francisco, presented a paper on "Paranasal Sinuses in Relation to Skull Injury, Subsequent Defects and Their Correction with Tantalum Plates." Discussed by Drs. I. Jerome Hauser, Detroit; Edgar M. Holmes, Boston, and Walter P. Work, San Francisco.

Dr. David D. DeWeese, Portland, Ore., read a paper on "Evaluation of the 'Dizzy' Patient." Discussed by Drs. Frank D. Lathrop, Boston; James W. McLaurin, Baton Rouge, La.; Lester Coleman, New York, and David D. DeWeese, Portland, Ore.

### Thursday, June 9—Morning

The following officers were elected: chairman, Dr. William H. Johnston, Santa Barbara, Calif.; vice chairman, Dr. Harold Hickey, Denver; secretary, J. Milton Robb, Detroit; executive committee, Dr. Fletcher D. Woodward, Charlottesville, Va.; Dr. Henry B. Orton, Newark, N. J., and Dr. William H. Johnston, Santa Barbara, Calif.; delegate, Dr. Gordon Harkness, Davenport, Iowa; alternate, Dr. C. H. McCaskey, Indianapolis; representative to Board of Governors of American College of Surgeons, Dr. Charles Blassingame, Memphis, Tenn.; chairman, Section Committee on Scientific Exhibit, James B. Costen, St. Louis; representatives to International Congress of Otolaryngology in London, July 18-23, 1949, Dr. Louis H. Clerf, Philadelphia, and Dr. Leroy Schall, Boston.

On motion of Dr. C. H. McCaskey, Indianapolis, seconded by Dr. Henry M. Scheer, New York, it was voted that the question of whether the Section meeting should consist of three days be referred to the executive committe for decision and action.

Dr. Henry B. Orton, Newark, N. J., read the chairman's address, entitled "The Future Laryngologist."

Dr. W. Likely Simpson, Memphis, Tenn., presented a paper on "The Ethmo-Spheno-Frontal Sinus Operation." Discussed by Drs. J. Milton Robb, Detroit; Sam E. Roberts, Kansas City, Mo., and W. Likely Simpson, Memphis, Tenn.

Drs. Sam E. Roberts and Frank S. Forman, Kansas City, Mo., presented a paper on "Direct Laryngoscopy: Simplified Technic." Discussed by Drs. Frederick A. Figi, Rochester, Minn.; Daniel S. Cunning, New York, and Sam E. Roberts, Kansas City, Mo.

Dr. Delmar F. Weaver, Detroit, read a paper on "Diagnosis and Treatment of Tumors of the Neck." Discussed by Drs. Louis H. Clerf, Philadelphia; Ralph J. McQuiston, Indianapolis; Henry B. Orton, Newark, N. J., and Delmar F. Weaver, Detroit.

## SECTION ON PEDIATRICS

WEDNESDAY AFTERNOON, JUNE 8, 1949

The meeting was called to order at 2 p. m. by the chairman, Dr. Woodruff L. Crawford, Rockford, Ill.

The first paper on the program was "Treatment of Acute Rheumatic Fever and Prevention of Recurrences," by Dr. Robert L. Jackson, Iowa City. This was discussed by Drs. William Weston Jr., Columbia, S. C.; John P. Hubbard, Philadelphia; May G. Wilson, New York; Lord Horder, Great Britain, and Dr. Robert L. Jackson.

A paper entitled, "The Treatment of Infection with New Antibiotics," by Drs. Perrin H. Long, Emanuel B. Schoenbach, Morton S. Byrer, Caroline A. Chandler and Eleanor A. Bliss, Baltimore, was presented by Dr. Perrin H. Long, and discussed by Drs. Vernon Knight, New York; Robert B. Lawson, Winston-Salem, N. C., and Perrin H. Long.

A paper entitled, "Three Day Fever: An Endemic Febrile Disease of Childhood, with Virus Studies," by Drs. Clarence H. Webb, Shreveport, La.; S. George Wolfe, New York, and Beatrice F. Howitt, Montgomery, Ala., was read by Dr. Clarence H. Webb and discussed by Drs. Thomas F. McNair Scott, Philadelphia; George J. Boines, Wilmington, Del., and Clarence H. Webb.

"Acute Conjunctivitis Caused by Hemophilus," by Drs. Dorland J. Davis and Margaret Pittman of Bethesda, Md., was presented by Dr. Davis and discussed by Drs. James C. Overall, Nashville, Tenn.; Samiye Argut, Ankara, Turkey; Thomas D. Allen, Chicago; Alson E. Braley, New York, and Dorland J. Davis.

"Congenital Obstruction of the Alimentary Tract" was read by Dr. William E. Anspach, Chicago, and discussed by Drs. Orvar Swenson, Boston; Mercer Blanchard, Columbus, Ga., and McLenmore Birdsong, Charlottesville, Va., with closing discussion by Dr. Anspach.

"Congenital Dislocation of the Hip Joint: Early Recognition and Prevention," by Dr. Vernon L. Hart, Minneapolis, was discussed by Drs. Russell C. Bond, Wheeling, W. Va.; Mayer S. DeRoy, Pittsburgh, and Charles C. Chapple, Philadelphia.

THURSDAY, JUNE 9—AFTERNOON

The following officers were elected: chairman, Dr. Margaret Mary Nicholson, Washington, D. C.; vice chairman, Dr. Adolph De Sanctis, New York; secretary, Dr. Wyman C. C. Cole, Detroit; delegate to House of Delegates of American Medical Association, Dr. William Weston Sr., Columbia, S. C.; alternate, Dr. Julius Hess, Chicago; representative on the Scientific Exhibit, Dr. Albert V. Stoesser, Minneapolis; executive committee, Dr. Margaret Mary Nicholson, Washington, D. C.; Dr. Woodruff L. Crawford, Rockford, Ill., and Dr. Stanley Gibson, Chicago.

Dr. Nicholson, serving as secretary, reported on a communication received, suggesting the transfer of the Abraham Jacobi Fund to a medical library, the John Ferrara Library in Chicago, and said that, after discussion, the Executive Committee had stated the opinion that the Fund should not be diverted to any other purpose than that for which it was established, i. e., for financial assistance to distinguished guests. The Executive Committee was also of the opinion that further funds should be solicited for this purpose, and also that the custodian be elected yearly.

On motion made by Dr. Harry M. Gilkey, seconded by Dr. James Overall, it was unanimously voted to keep the Fund intact, that contributions should be solicited and that Dr. Hugh Dwyer of Kansas City, the present custodian, be reelected.

On motion made by Dr. Gilbert Levy and seconded by Dr. Weston, it was unanimously voted to introduce a resolution in the House of Delegates to the effect that, whereas 75 per cent of the care of children is in the hands of the general practitioner and about one third of the work of the general practitioner is in the field of pediatrics, there should be developed a regular examination in pediatrics by the various state boards of medical licensure, to encourage students and interns in informing themselves on the care of children, with the suggestion that a practicing pediatrician assist in the framing of such an examination.

A symposium on congenital heart disease followed, including the following papers:

"Congenital Heart Disease from the Pediatric View," by Dr. Stanley Gibson, Chicago.

"The Diagnosis and the Differential Diagnosis of Congenital Heart Defects Amenable to Surgery," by Dr. Helen B. Taussig, Baltimore.

"Common Cardiac Defects Which Can Be Treated by Surgery: Discussed from Standpoint of Functional Pathology," by Dr. Jesse E. Edwards, Rochester, Minn.

"Angiocardiographic Examples," by Dr. John D. Keith, Toronto, Canada.

"Problems Encountered in Surgical Treatment of Patients with Coarctation of the Aorta," by Dr. Alfred Blalock, Baltimore.

The symposium was discussed by Dr. John C. Jones, Los Angeles, who presented a motion picture on "Coarctation of the Aorta."

FRIDAY, JUNE 10—AFTERNOON

A paper on "Medical Implications and Applications of Radioisotopes" was read by Dr. George M. Lyon of Alexandria, Va., and discussed by Drs. Malcolm W. Mason and Fred R. Lang of Bethesda, Md., with closing discussion by Dr. Lyon.

"Factors Responsible for Laryngeal Obstruction in Infants," by Dr. Paul H. Holinger, Chicago, was presented in the form of a motion picture, with discussion by Drs. Louis H. Clerf and Waldo E. Nelson, Philadelphia, and Dr. E. Clarence Rice, Washington, D. C., with closing discussion by Dr. Holinger.

"Asphyxia of the Newborn" was presented by Dr. C. C. Cole of Detroit, with discussion by Drs. Stewart H. Clifford, Brookline, Mass.; William F. O'Donnell, Washington, D. C.; James B. Stone, Richmond, Va., and W. Allen Conroy, Chicago.

"Evils of Thumb Sucking" was presented by Dr. Charles Hendee Smith, New York, with discussion by Drs. Henry H. Work Jr., Arlington, Va.; Argimiro Brachamonte, Berquisimeto, Venezuela; Marjorie Horner, Wema, Belgian Congo, and Dr. Smith.

Announcement was made of the Sixth International Pediatrics Congress to be held in Zurich, Switzerland, on July 24-28, 1950, and the Pan-American Pediatrics Congress in Mexico City on Nov. 1-4, 1949.

Dr. Frank Howard Richardson, Asheville, N. C., read a paper entitled, "Breast Feeding Comes of Age," which was discussed by Drs. Alicia Gallaga Romero, Mexico; M. Hines Roberts, Atlanta, Ga., and Dr. Richardson.

"Chemotherapy of Childhood Cancer Including Leukemia" was read by Dr. Sidney Farber of Boston and discussed by Drs. Murray Shear, Bethesda, Md.; Lewis Katz Albert, Washington, D. C.; Roswell D. Johnson, New Orleans; S. D. Mills, Rochester, Minn., and Oscar Brentwood Hunter Jr., Washington, D. C., with closing discussion by Dr. Farber.

## SECTION ON EXPERIMENTAL MEDICINE AND THERAPEUTICS

WEDNESDAY, JUNE 8—AFTERNOON

The meeting was called to order at 2 p. m. by the chairman, Dr. Dwight L. Wilbur, San Francisco.

Dr. Chester S. Keefer, Boston, read a paper on "Dosage Forms of Penicillin." This paper was discussed by Drs. Dwight L. Wilbur, San Francisco; Eli Levin, Rochester, N. Y., and Charles Fox, New York.

Dr. Walsh McDermott, New York, read a paper on "The Relation of Streptomycin Dosage to Toxicity and to Emergence of Resistant Organisms." This paper was discussed by Drs. Harry F. Dowling and John R. Barnwell, Washington, D. C.

Dr. Wesley W. Spink, Minneapolis, read a paper on "Aureomycin: Present Status in the Treatment of Human Infections." This paper was discussed by Drs. Martin H. Siefert, Wilmette, Ill.; David I. Macht, Baltimore; Carl V. Moore, St. Louis, and Harold A. Lyons, St. Albans, Long Island, N. Y.

Dr. Joseph E. Smadel, Washington, D. C., read a paper on "Clinical Use of the New Antibiotic Chloramphenicol (Chloromycetin)." This paper was discussed by Drs. Theodore E.

Woodward, Baltimore; Harold T. Hyman, New York; Harry Huber, Chicago, and Francis H. Redewill, San Francisco.

Dr. Norman H. Topping, Bethesda, Md., read a paper on "Research on the Common Cold." There was no discussion of this paper.

Dr. Hilary Koprowski, Pearl River, N. Y., read a paper on "Antiserum in Rabies: Use of Hyperimmune Antirabies Serum Concentrates in Experimental Rabies and Indications for Its Use After Exposure of Humans to Rabies." This paper was discussed by Dr. Karl Habel, Bethesda, Md.

### THURSDAY, JUNE 9—AFTERNOON

The following officers were elected: chairman, Dr. McKeen Cattell, New York; vice chairman, Dr. James A. Greene, Houston, Texas; secretary, Dr. Carl V. Moore, St. Louis; executive committee, Drs. Walter Bauer, Boston; Dwight Wilbur, San Francisco, and McKeen Cattell, New York; delegate, Dr. Edgar V. Allen, Rochester, Minn.; alternate, Dr. Charles M. Gruber, Philadelphia; representative to the Committee on Scientific Exhibits, Dr. Robert W. Wilkins, Boston.

Dr. Dwight L. Wilbur, San Francisco, read a paper on "The Clinical Management of the Patient with Fatigue and Nervousness." There was no discussion of this paper.

Dr. Edward H. Reissner, New York, read a paper by the late Dr. Randolph West, New York, on "The Treatment of Addisonian Pernicious Anemia with Vitamin $B_{12}$." This paper was discussed by Drs. William J. Darby, Nashville, Tenn., and Byron E. Hall, Rochester, Minn.

Drs. Edward H. Reinhard and James T. Good, St. Louis, and Edward Martin, New Britain, Conn., presented a paper on "Chemotherapy of Malignant Neoplastic Diseases." This paper was discussed by Drs. J. M. Stickney, Rochester, Minn.; William Dameshek, Boston, and M. J. Shear, Bethesda, Md.

Dr. John H. Talbott, Buffalo, read a paper on "The Use of Lithium Salts as a Salt Substitute." This paper was discussed by Drs. Henry A. Schroeder, St. Louis, and McKeen Cattell, New York.

Dr. Cyril M. MacBryde, St. Louis, read a paper on "Modern Treatment of Diabetes with Special Reference to the Use of New Modified Protamine Insulin." This paper was discussed by Dr. Henry Dolger, New York.

### FRIDAY, JUNE 10—MORNING

Joint meeting with Section on Internal Medicine.

## SECTION ON PATHOLOGY AND PHYSIOLOGY

### WEDNESDAY, JUNE 8—MORNING

The meeting was called to order at 9 a. m. by the chairman, Dr. George E. Wakerlin, Chicago.

Dr. Charles A. Doan, Columbus, Ohio, presented the subject, "The Pathologic Physiology of the Spleen." This subject was discussed by Drs. Carroll Birch, Chicago; Edwin Hirsch, Chicago; William Dameshek, Boston; Frank Lahey, Boston; Harry Corper, Denver, and George E. Wakerlin, Chicago.

Dr. William Dameshek, Boston, presented a paper on "The Physiopathology and Course of Polycythemia Vera." This paper was discussed by Drs. Paul Reznikoff, New York; Paul Klemperer, New York; Perk Lee Davis, Philadelphia; Edward H. Reinhard, St. Louis; F. W. S. Modern, Van Nuys, Calif., and John Lawrence, Berkeley, Calif.

Dr. Julius H. Comroe Jr., Philadelphia, presented the subject, "Recent Advances in the Physiology of Respiration with Particular Reference to Oxygen Therapy." This paper was discussed by Drs. Alvan L. Barach, New York; Carl Wiggers, Cleveland, and Stanley J. Sarnoff, Boston.

Dr. Henry Miles, Boston, read a paper by Dr. Jacob E. Finesinger on "The Clinical Physiology of the Psychoneuroses." This paper was discussed by Drs. Richard M. Brickner, New York; Roland P. Mackay, Chicago; Mortimer Sackler, New York; M. M. Harris, New York; O. L. Friedman, New York, and George E. Wakerlin, Chicago.

### THURSDAY, JUNE 9—MORNING

The following officers were elected: chairman, Dr. Frank W. Konzelman, Atlantic City; vice chairman, Dr. A. S. Giordano, South Bend, Ind.; secretary, Edwin F. Hirsch, Chicago; executive committee, Dr. Alvin Foord, Pasadena, Calif.; Dr. George E. Wakerlin, Chicago, and Dr. Frank W. Konzelman, Atlantic City, N. J.; delegate, Dr. L. W. Larson, Bismarck, N. D.; alternate, Dr. Harry J. Corper, Denver.

After discussion concerning the advisability of changing the name of the section, it was moved, duly seconded, put to a vote and carried that the name remain as at present.

Dr. George E. Wakerlin, Chicago, read his chairman's address.

Dr. Bernard Steinberg, Toledo, Ohio, read a paper on "Studies of Production and Distribution of Leukocytes and Platelets: Demonstration of the Expulsion Factor for Leukocytes." This paper was discussed by Drs. Harry J. Corper, Denver; Jacob E. Pinzen, Philadelphia, and George E. Wakerlin, Chicago.

Drs. Henry Horn, Leonard E. Field, Simon Dack and Arthur M. Master, New York, presented a paper on "The Pathologic and Physiologic Aspects of Acute Coronary Insufficiency: An Analysis of Twenty-five Cases of Subendocardial Necrosis." This paper was discussed by Drs. Paul Klemperer, New York; Arthur M. Master, New York; Irving Graef, New York; Jacob Werne, New York, and Theodore Curfee, Garden City, N. Y.

Dr. H. Russell Fisher, Los Angeles, read a paper on "The Histopathology of Scleroma." This paper was discussed by Drs. Paul Klemperer, New York, and Frank W. Konzelman, Atlantic City, N. J.

Dr. Irving Graef, New York, read a paper on "Cardiac Lesions in Rheumatoid Arthritis." This paper was discussed by Dr. David Klink, Los Angeles.

### FRIDAY, JUNE 10—MORNING

The joint meeting of the Section on Pathology and Physiology with the Section on Gastro-Enterology and Proctology met in the Wedgewood Room, Chelsea Hotel, at 9 a. m., Dr. George E. Wakerlin presiding.

A paper on "Acute and Chronic Pancreatitis," by Dr. A. C. Ivy, Chicago, was not given, because Dr. Ivy was unable to be present.

Dr. J. Peerman Nesselrod, Evanston, Ill., and Dr. Jay M. Garner, Winnetka, Ill., presented a motion picture in color of "Chronic Ulcerative Colitis: Proctoscopic Appearance." This presentation was discussed by Drs. J. A. Bargen, Rochester, Minn.; Sidney A. Portis, Chicago; D. N. Silverman, New Orleans; William A. Swalm, Philadelphia; Jay M. Garner, Rochester, Minn., and Otto De Muth, Vancouver, British Columbia, Canada.

Dr. David State, Minneapolis, read a paper on "An Attempt to Identify Likely Precursor Groups of Gastric Cancer." This paper was discussed by Drs. Russell H. Morgan, Baltimore, and Alexander Brunschwig, New York.

Dr. Edward B. Benedict, Boston, read a paper on "The Value of Gastric Biopsy as Obtained Through the Flexible Operating Gastroscope." This paper was discussed by Drs. H. J. Moersch, Rochester, Minn.; Cecil O. Patterson, Dallas, Texas, and Louis E. Marshall, New York.

Dr. Franklin M. Hanger, New York, read a paper on "Diagnostic Problems in Jaundice." This paper was discussed by Drs. Richard B. Capps, Chicago; John R. Neefe, Philadelphia, and Hans Schiff, Lousiana.

## SECTION ON NERVOUS AND MENTAL DISEASES

### WEDNESDAY, JUNE 8—AFTERNOON

The meeting was called to order at 2 p. m. by the chairman, Dr. Francis J. Gerty, Chicago.

The paper entitled "Spontaneous Nontraumatic Hematomas" was read by Dr. Michael Scott, Philadelphia. The discussants were Drs. J. Rudolph Jaeger, Philadelphia; H. C. Voris, Chicago, and Michael Scott, Philadelphia.

Dr. A. Earl Walker, Baltimore, read a paper entitled "The Place of Neurologic Surgery in the Treatment of Epilepsy." Discussed by Dr. John E. Scarff, New York, and Dr. A. Earl Walker, Baltimore.

A paper by Drs. William H. Sweet and Stanley J. Sarnoff, Boston, entitled "A Clinical Method for Recording Internal Carotid Pressure: Significance of Changes During Carotid Occlusion," was read. Discussed by Drs. Henry A. Shenkin, Philadelphia; Arthur Ecker, Syracuse; Stanley J. Sarnoff, Boston, and William H. Sweet, Boston.

A paper on "The Treatment of Arnold-Chiari Malformation in Adults" was presented by Dr. W. James Gardner, Cleveland. The discussants were Drs. Ben W. Lichtenstein, Chicago; Jerome F. Grunnagle, Pittsburgh; Roland P. Mackay, Chicago; Michael Scott, Philadelphia; William H. Sweet, Boston, and W. James Gardner, Cleveland.

A paper entitled "The Effect of Head Posture on Cerebrospinal Fluid Manometrics in Cervical Lesions: A New Diagnostic Test" was presented by Drs. Lawrence I. Kaplan and Foster Kennedy, New York. Discussed by Luman E. Daniels, Denver, and Foster Kennedy, New York.

Dr. Joe R. Brown, Minneapolis, read a paper entitled "Localizing Cerebellar Syndromes." The discussants were Drs. Benjamin H. Balser, New York; Averill Stowell, Tulsa, Okla., and Joe R. Brown, Minneapolis.

### THURSDAY, JUNE 9—AFTERNOON

The following officers were elected: chairman, Dr. Frederick R. Moersh, Rochester, Minn.; vice chairman, Dr. A. E. Bennett, Berkeley, Calif.; secretary, Dr. Francis Forster, Philadelphia; delegate, Dr. Percival Bailey, Chicago; alternate, Dr. Luman E. Daniels, Denver; representative to the American Board of Psychiatry and Neurology, Dr. George N. Raines, Bethesda, Md.

Dr. Hans H. Reese, Madison, Wis., then reported on the work accomplished at the meeting of the House of Delegates.

Dr. Francis M. Forster, Philadelphia, then read a report from the Secretary of the American Board of Psychiatry and Neurology.

Dr. Francis M. Forster, Philadelphia, then read a report on a request for a subspecialty board in pediatric psychiatry.

Dr. K. B. Corbin, Rochester, Minn., then moved that the following resolution be adopted:

> The Section on Nervous and Mental Diseases of the American Medical Association opposes the formation of any new subspecialty board of the American Board of Psychiatry and Neurology at this time. If any certification is given in a subspecialty in the fields of neurology and/or psychiatry, the certification should be given by the American Board of Psychiatry and Neurology, Inc., only after the candidate has received certification in psychiatry, neurology, or both, by the American Board of Psychiatry and Neurology.

The resolution was voted on and carried.

Dr. Francis J. Gerty gave the chairman's address entitled "The Scope and Relationship of Psychiatry in Medicine."

Dr. Douglas Goldman, Cincinnati, presented a paper entitled "Treatment of Neurosyphilis with Penicillin." Discussed by Drs. George D. Gammon and John H. Stokes, of Philadelphia; Dr. Irving J. Sands, Brooklyn; Dr. Roland Mackay, Chicago, and Dr. Douglas Goldman, Cincinnati.

A paper entitled "The Evaluation of Artane in the Treatment of Parkinsonism" was presented by Dr. Kendall B. Corbin of Rochester, Minn. This subject was discussed by Dr. Peter G. Denker, New York; Roland P. Mackay, Chicago, and Dr. K. B. Corbin, Rochester, Minn.

A paper entitled "The Psychiatric Manifestations of Certain Convulsive Disorders" by Dr. Richard L. Masland, Winston-Salem, N. C., was presented. Discussed by Drs. Calvin S. Drayer, Philadelphia; Francis M. Forster, Philadelphia, and Richard L. Masland, Winston-Salem, N. C.

A paper by Dr. Joseph L. Fetterman, Cleveland, entitled "Mesantoin and Combined Therapy, A Three Year Study" was presented. Discussed by Drs. H. Houston Merritt, New York; William Shapera, Philadelphia; H. E. Cohen, New York, and Joseph L. Fetterman, Cleveland.

Dr. Andrew J. Leemhuis, Minneapolis, read a paper entitled "Retraining Therapy in Neurologic Diseases." Discussed by Drs. Pearce Bailey, Washington, D. C.; Hans H. Reese, Madison, Wis., and Andrew J. Leemhuis, Minneapolis.

### FRIDAY, JUNE 10—AFTERNOON

A telegram from Dr. Herbert A. Perry, Medical Lake, Wash., was read to the section referring to his absence; Dr. Perry was to have presented the first paper at this meeting.

Drs. James Purtell, Milwaukee, and Eli Robbins, Boston, presented a paper entitled "Clinical Aspects of Hysteria: A Study of 100 Cases and 100 Control Subjects." Discussed by Drs. J. M. Nielsen, Los Angeles; R. L. Masland, Winston-Salem, N. C.; Charles Rupp, Philadelphia; Frederick C. Redlich, New Haven, Conn., and James Purtell, Milwaukee.

A paper entitled "Ictal and Nonictal Psychiatric Disorder in Temporal Lobe Epilepsy" by Dr. Frederick A. Gibbs, Chicago, was read. Discussed by Drs. R. L. Masland, Winston-Salem, N. C.; Gordon K. Damman, St. Paul; Roland P. Mackay, Chicago; J. M. Nielsen, Los Angeles, and Frederick A. Gibbs, Chicago.

Dr. Paul H. Hoch, New York, read a paper entitled "Theoretical Aspects of Prefrontal Lobotomy and Similar Operations." Discussed by Drs. A. R. Vonderahe, Cincinnati; Walter Freeman, Washington, D. C.; Foster Kennedy, New York, and Paul H. Hoch, New York.

A paper entitled "Practical Considerations in the Treatment of the Mentally Ill" was read by Dr. Irving J. Sands, New York. Discussed by Dr. George N. Raines, Bethesda, Md.; Dr. Joseph C. Yaskin, Philadelphia; Dr. Paul H. Hoch, New York, and Dr. Irving J. Sands, New York.

Drs. Frederick Lemere and Paul O'Hallaren, Seattle, presented a paper entitled "Intravenous Pentathol® in the Treatment of Alcoholism." Discussed by Drs. Robert V. Seliger, Baltimore, J. M. Nielsen, Los Angeles, and Frederick Lemere.

## SECTION ON DERMATOLOGY AND SYPHILOLOGY

### WEDNESDAY, JUNE 8—AFTERNOON

The meeting was called to order at 2 p. m. by the chairman, Dr. Anthony C. Cipollaro, New York.

Dr. Everett C. Fox, Dallas, Texas, section delegate, gave a report on the Interim Session of the House of Delegates which was held in St. Louis in November 1948, and the meeting held June 6-7, 1949, at Atlantic City.

Dr. Francis W. Lynch, St. Paul, read his report as section representative on the Scientific Exhibit Committee.

Dr. George K. Lewis, New York, presented the report of the American Board of Dermatology and Syphilology.

Dr. Nelson Paul Anderson, Los Angeles, read the report of the nominating committee.

Dr. J. G. Downing, Boston, on behalf of the Committee on International Congress, gave a progress report to the effect that present world conditions did not permit an international congress but that, when one is held, it would be desirable to hold it in Europe.

Dr. Clinton W. Lane, St. Louis, secretary, reported concerning the decision of the Council on Scientific Assembly to limit the meeting of sections to two days instead of the customary three days, the reason being the difficulty in securing adequate housing. He stated that he was chagrined to learn that only one other section besides the Section on Dermatology and Syphilology had finally been limited to two days, the other sections having protested to such an extent that they were given the third day. The secretary said that he had an oral promise that the section would receive consideration in plans for the 1950 convention in San Francisco.

Dr. Anthony C. Cipollaro, New York, read the chairman's address, entitled "Dermatology and Syphilology in a Modern Medical Program."

Dr. W. B. Guy, Pittsburgh, read a paper entitled "Protein Deficiency in Cutaneous Disease." Discussed by Drs. F. J. Eichenlaub, Washington, D. C.; John H. Lamb, Oklahoma

City, Okla.; Michael Wohl, Philadelphia; S. Tashian, Seattle, Wash., and W. B. Guy, Pittsburgh.

Dr. J. G. Downing, Boston, presented a paper on "Simulation and Self Infliction in Industrial Dermatology." Discussed by Drs. J. W. Jordon, Buffalo; Alfred Hollander, Springfield, Mass.; Theodore Cornbleet, Chicago, and J. G. Downing, Boston.

Dr. Leon Goldman, Cincinnati, read a paper entitled "The Dermatologic Aspects of Insect Repellents and Toxicants." Discussed by Drs. Theodore Cornbleet, Chicago; Bertram Shaffer, Philadelphia; Bernard Appel, Lynn, Mass., and Leon Goldman, Cincinnati.

Dr. H. M. Robinson Jr., Baltimore, presented a paper, "A Comparative Analysis of the Muco-Cutaneous-Ocular Syndromes." Discussed by Drs. Helen O. Curth, New York; H. M. Robinson Sr., Baltimore; Walter Lever, Boston, and H. M. Robinson Jr., Baltimore.

Drs. V. M. Henington, Frederick Grieshaber and J. K. Howles, New Orleans, presented a paper entitled "Dermatoses of the Colored Race." Discussed by Drs. T. W. Murrell Jr., Richmond, Va.; George K. Lewis, New York; E. F. Corson, Philadelphia, and V. M. Henington, New Orleans.

### Thursday, June 9—Afternoon

The following officers were elected: chairman, Dr. Clinton W. Lane, St. Louis (1 year); vice chairman, Dr. Norman Epstein, San Francisco (1 year); secretary, Dr. John H. Lamb, Oklahoma City (3 years); executive committee: Drs. Henry E. Michelson, Minneapolis (1 year); Anthony C. Cipollaro, New York (2 years), and Clinton W. Lane, St. Louis (3 years); delegate, Everett C. Fox, Dallas, Texas (1 year); alternate, Leonard Weber, Chicago (1 year); representative to American Board of Dermatology and Syphilology, George K. Lewis, New York (3 years); representative on Scientific Exhibit Committee, Francis W. Lynch, St. Paul (3 years).

On motion made by Dr. J. G. Downing, Boston, and seconded by Dr. Francis W. Lynch, St. Paul, it was voted that the members of the Section of Dermatology and Syphilology instruct the incoming secretary to notify, in writing, the Council on Scientific Assembly that the curtailment of the session was resented and to demand that the original period of three days be restored.

Dr. Wallace Wilson, Los Angeles, presented the following resolution:

> Whereas, Approximately 30 per cent of the incidence of human disease is dermatologic in nature, while only 3 per cent of medical teaching is pointed in that direction; and
>
> Whereas, The delineation between dermatologic and nondermatologic disorders is at least as sharp as that governing any other specialty; and
>
> Whereas, Dermatology is now successfully attracting research and clinical personnel in sufficient quantity and quality to enable it to fulfill adequately its obligations to humanity and to the practice of medicine whenever it is given the opportunity; now, be it
>
> *Resolved,* By the Section on Dermatology and Syphilology of the American Medical Association that dermatology shall take its rightful place as a full and separate specialty in all American localities and institutions; and be it further
>
> *Resolved,* That the specialty of dermatology shall be given physical, intellectual, moral and financial support commensurate with its proper position leading to the adequate control of human morbidity; and be it further
>
> *Resolved,* That all American dermatologists pledge their continued attention and activity to this end within their separate spheres of influence.

It was voted that the foregoing resolution be sent direct to Dr. George F. Lull, Secretary and General Manager of the American Medical Association, with the request that he transmit it direct to the Board of Trustees.

Dr. C. Guy Lane, Boston, delivered the Distinguished Lecture in Dermatology, entitled "The Development of Standards in Dermatology."

On behalf of the section, Dr. Anthony C. Cipollaro, New York, chairman of the section, presented a scroll to Dr. C. Guy Lane.

Dr. L. P. Barker, New York, read a paper entitled "Rickettsialpox." Discussed by Drs. Nelson Paul Anderson, Los Angeles; Eugene Traugott Bernstein, New York, and L. P. Barker, New York.

Drs. T. H. Sternberg, D. J. Perry and Paul LeVan, Los Angeles, presented a paper on "Comparative Activity in Human Subjects of Antihistamine Drugs as Determined by Histamine Iontophoresis." Discussed by Drs. D. M. Pillsbury, Philadelphia, and T. H. Sternberg, Los Angeles.

Drs. George A. Waldriff, Jeff Davis and G. M. Lewis, New York, presented a paper entitled "Antihistamine Therapy in Dermatology." Discussed by Drs. D. M. Ruch, Milwaukee; F. A. Ellis, Baltimore; Charles S. D'Avanzo, Springfield, Mass.; Stephan Epstein, Marshfield, Wis.; G. H. Curtis, Cleveland, and Jeff Davis, New York.

Dr. E. F. Traub, New York, read a paper entitled "The Benign Pigmented Epithelial Nevus." Discussed by Drs. W. M. Sams, Miami, Fla.; Hamilton Montgomery, Rochester, Minn., and E. F. Traub, New York.

Dr. M. J. Strauss, New Haven, Conn., read a paper on "Spindle Cell Epidermoid Carcinoma." Discussed by Drs. M. D. Marcus, St. Louis; Hamilton Montgomery, Rochester, Minn.; Walter Lever, Boston, and M. J. Strauss, New Haven, Conn.

Drs. H. N. Cole Jr., Cleveland, and W. R. Hubler, Corpus Christi, Texas, presented a paper entitled "Misplaced Mongolian Spot." Discussed by Drs. S. R. Mercer, Fort Wayne, Ind.; Herman Beerman, Philadelphia; F. A. Ellis, Baltimore; Hamilton Montgomery, Rochester, Minn., and H. N. Cole Jr., Cleveland.

## SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

### Wednesday, June 8—Morning

The meeting was called to order at 9 a. m. by the chairman, Dr. Oscar A. Sander, Milwaukee.

In introducing a Symposium on Air Pollution (Smog), Dr. W. C. L. Hemeon, Pittsburgh, read a paper on "The Aspects of Smog: (*a*) Chemical; (*b*) Topographic; (*c*) Meteorologic."

Dr. P. L. Magill, Stanford, Calif., presented a paper entitled "An Investigation of Smog in Los Angeles."

A paper entitled "Causes, Constituents and Physical Effects of Smog Involved in Specific, Dramatic Episodes (Donora; Meuse River Valley)," was read by Dr. H. H. Schrenk, Bethesda, Md.

Dr. L. C. McCabe, Los Angeles, presented a paper entitled "Administration of an Air Pollution Control Program."

Dr. Robert A. Kehoe, Cincinnati, summarized the essays.

Discussants of these papers were Drs. Rufus Reeves, Philadelphia; Joseph Shilen, Philadelphia; Francis M. Pottenger, Monrovia, Calif.; William Lewis Jr., New York; John L. Hodges, Philadelphia; C. A. Mills, Cincinnati; James Townsend, Washington, D. C., and John H. Fuulger, Wilmington, Del.

### Thursday, June 9—Morning

The following officers were elected: chairman, Carl N. Neupert, Madison, Wis.; vice chairman, Rutherford T. Johnstone, Los Angeles, and secretary, Gene Felton.

Dr. Oscar A. Sander, Chicago, read a paper entitled "The General Aspects of Pneumoconiosis and Infection."

"The Energetic Theory of Silicosis" was presented by Dr. Silas M. Evans, Milwaukee.

Dr. H. A. Slesinger, Winder, Pa., read a paper entitled "Anthracosilicosis in Bituminous Coal Miners: A Clinical Survey." Discussants were Drs. Arthur Vorwald, Saranac, N. Y., and Frank Princi, Denver.

A paper entitled "Pulmonary Functional Impairment in Anthracosilicosis" was presented by Drs. Hurley L. Motley, Burgess Gordon, Leonard P. Lang and Peter T. Theodos, Philadelphia.

Dr. George A. Wright, Saranac, N. Y., read a paper entitled "Disability Evaluation in Industrial Pulmonary Disease." Discussed by Robert Bruce, Rochester, N. Y., and J. J. Burrascano, New York.

### FRIDAY, JUNE 10—MORNING

Dr. George M. Wheatley, New York, read a paper entitled "Why School Health Service?"

A paper was read by Dr. Hugh R. Leavell, Boston, entitled "Federal Health Services: Recommendations of the Hoover Commission."

Dr. Thomas Francis Jr., Ann Arbor, Mich., read a paper entitled "The Family Doctor: An Epidemiologic Concept."

A paper entitled "The Role of the Physician in Public Health Progress" was read by Dr. Leonard A. Scheele, Washington, D. C.

Dr. Herman E. Hilleboe, Albany, N. Y., presented a paper entitled "The Exact Diagnosis of Pulmonary Tuberculosis."

## SECTION ON UROLOGY

### WEDNESDAY, JUNE 8—MORNING

The meeting was called to order at 9:15 a. m., by the chairman, Dr. Hamilton W. McKay, Charlotte, N. C.

In the unavoidable absence of Dr. Reed M. Nesbit, Ann Arbor, Mich., the chairman appointed Dr. William Herbst, Washington, D. C., to serve on the executive committee.

The following papers were presented:

"Leukoplakia of the Renal Pelvis," by Dr. Lowrain E. McCrea, Philadelphia.

"Papillary Necrosis of the Kidney: A Clinical and Experimental Correlation," by Dr. E. E. Muirhead, Dallas, Texas.

"Observations on the Electrolyte Pattern of the Blood Following Bilateral Ureterointestinal Anastomosis," by Drs. D. O. Ferris and H. M. Odel, Rochester, Minn.

These three papers were discussed by Drs. Hugh J. Jewett, Baltimore; Victor F. Marshall, New York; Franklin Farman, Whittier, Calif.; Rubin Flocks, Iowa City; Lowrain E. McCrea, Philadelphia; E. E. Muirhead, Dallas, Texas, and H. M. Odel, Rochester, Minn.

Drs. James C. Kimbrough and Joseph C. Denslow, Washington, D. C., presented a paper on "Urinary Tract Calculi in Recumbent Patients."

Dr. David S. Cristol, Philadelphia, read a paper entitled "Radioactive Urine and Urinary Tract Calculi."

Discussion on papers of Drs. Kimbrough and Denslow and Dr. Cristol by Drs. Rubin Flocks, Iowa City; John F. McCuskey, Clarksburg, W. Va.; Henry Sangree, Philadelphia; James C. Kimbrough, Washington, D. C., and David S. Cristol, Philadelphia.

Dr. Grayson Carroll, St. Louis, presented a paper on "Gantrosan (NU-445): An in Vitro and in Vivo Study in Urinary Infections."

Dr. J. Robert Rinker, Augusta, Ga., read a paper on "The Effect of Streptomycin on the Tuberculous Ureter."

The papers of Drs. Carroll and Rinker were discussed by Drs. E. Craig Coats, New York; Louis C. Roberts, Durham, N. C.; Seymour Wilhelm, New York; Edward Cook, Rochester, Minn.; Wm. Herbst, Washington, D. C.; Ralph H. Jenkins, New Haven, Conn.; Grayson Carroll, St. Louis, and J. Robert Rinker, Augusta, Ga.

### THURSDAY, JUNE 9—MORNING

Dr. A. I. Dodson, Richmond, Va., read the report of the activities of the American Board of Urology, which was received and filed.

The following officers were elected: chairman, Dr. Edward N. Cook, Rochester, Minn. (1 year); vice chairman, Dr. Hugh J. Jewett, Baltimore (1 year); secretary, Earl E. Ewert, Boston (3 years); delegate, Dr. Jay J. Crane, Los Angeles (1 year); alternate, Dr. Rex Van Dusen, Dallas, Texas (1 year); representatives on Scientific Exhibits, Drs. John H. Morrissey, New York (1 year); Roger W. Barnes, Los Angeles (1 year), and Wm. W. Scott, Baltimore (1 year); executive committee, Drs. Reed M. Nesbit, Ann Arbor, Mich. (1 year); Hamilton W. McKay, Charlotte, N. C. (2 years), and Edward N. Cook, Rochester, Minn. (3 years).

The members stood in silent tribute to the memory of Dr. Roy B. Henline, New York, recently deceased.

The following papers were presented:

"Excretory Urography Versus Retrograde Urography: Their Respective Advantages and Indications, with Illustrated Cases, by Drs. J. Byron Beare and Carl A. Wattenberg, St. Louis.

"Significant Scrotal Swellings", by Dr. R. Theodore Berman, Los Angeles.

The papers of Drs. Beare and Wattenberg were discussed by Drs. Walter M. Kearns, Milwaukee; Monroe Wolf, New Orleans; James C. Kimbrough, Washington, D. C.; J. Byron Beare, St. Louis, and R. Theodore Bergman, Los Angeles.

Drs. Waltman Walters and Randall G. Sprague, Rochester, Minn., presented a paper entitled "Physiologic and Chemical Changes Associated with Hyperfunctioning Tumors of the Suprarenal Cortex." Discussed by Drs. M. M. Melicow, New York; Hugh J. Jewett, Baltimore, and Waltman Walters, Rochester, Minn.

Dr. Hamilton W. McKay, Charlotte, N. C., read the chairman's address.

The following papers were presented:

"Analysis of the Treatment of Bladder Tumors," by Drs. W. Calhoun Stirling and J. E. Ash, Washington, D. C.

"Papillomas of the Bladder," by Drs. Herman L. Kretschmer and Edward A. Stika, Chicago.

"Vesical Neoplasms of the Female Bladder: A Suggested Surgical Technic," by Drs. J. Sydney Ritter and Leo A. Shifrin, New York.

The papers of Drs. Stirling and Ash, Drs. Kretschmer and Stika, and Drs. Ritter and Shifrin were discussed by Drs. Ernest Rupel, Indianapolis; Thomas J. Kirwin, New York; G. J. Thompson, Rochester, Minn.; David Worgan, Washington, D. C.; M. M. Melicow, New York; W. Calhoun Stirling, Washington, D. C.; Herman L. Kretschmer, Chicago, and Leo A. Shifrin, New York.

### FRIDAY, JUNE 10—MORNING

A panel discussion was conducted with the following participants answering questions that had previously been submitted: Drs. R. H. Flocks, Iowa City; Rex Van Dusen, Dallas, Texas; Jay J. Crane, Los Angeles, and William W. Scott, Baltimore, with Dr. G. J. Thompson, Rochester, Minn., acting as moderator.

The following papers were presented:

"Prostatic Cancer: Further Investigation of Hormonal Relationships," by Drs. Herbert Brendler, W. E. Chase and William W. Scott, Baltimore.

"Carcinoma of the Prostate Gland: Results with Conservative Management," by Drs. Lloyd R. Reynolds, Thomas L. Schulte and Howard J. Hammer, San Francisco.

"Carcinoma of the Prostate: Review of 150 Cases," by Dr. William Baurys, Sayre, Pa.

The papers of Drs. Brendler, Chase and Scott, Drs. Reynolds, Schulte and Hammer and Dr. Baurys were discussed by Drs. S. W. Mulholland, Philadelphia; William Herbst, Washington, D. C.; G. J. Thompson, Rochester, Minn.; Ernest F. Hock, Binghamton, New York; Herbert Brendler, Baltimore; Lloyd R. Reynolds, San Francisco, and William Baurys, Sayre, Pa.

The following papers were presented:

"Postoperative Urinary Incontinence," by Dr. Edwin Davis, Omaha.

"The Technic for Immediate Diagnosis and Management of Vesical or Urethral Perforations in the Course of Transurethral Procedures," by Dr. Herbert R. Kenyon, New York.

"Problems Associated with Transurethral Relief of Bladder Neck Obstruction," by Dr. John H. Dougherty, Knoxville, Tenn.

The papers of Drs. Davis, Kenyon and Dougherty were discussed by Drs. Dean Makowski, New York; T. A. Morrissey, New York; David M. Davis, Philadelphia; Leon Herman, Philadelphia; Ernest F. Hock, Binghamton, N. Y.; Ralph H. Jenkins, New Haven, Conn.; Herbert R. Kenyon, New York, and John H. Dougherty, Knoxville, Tenn.

## SECTION ON ORTHOPEDIC SURGERY

### Wednesday, June 8—Morning

The meeting was called to order at 9 a. m. by the chairman, Dr. David M. Bosworth, New York.

Drs. Steven M. Horvath and Joseph L. Hollander, Philadelphia, presented a paper on "The Effect of Vasodilating and Vasoconstricting Drugs on the Temperature of Joints and Related Structures." Discussed by Drs. A. R. Shands Jr., Wilmington, Del.; Paul C. Colonna, Philadelphia, and Steven M. Horvath, Philadelphia.

Mr. Douglas H. Collins, Leeds, England, read a paper on "The Pathologic Distinction Between Osteoarthritis and Osteophytosis of the Spine with a Note on the Morbid Anatomy of Ankylosing Spondylitis." Discussed by Drs. Robert P. Kelly Jr., Atlanta, Ga.; Edward L. Compere, Chicago; Gerry Hough, Springfield, Mass.; Lenox D. Baker, Durham, N. C.; Lee A. Hadley, Syracuse, N. Y.; David M. Bosworth, New York, and Douglas H. Collins, Leeds, England.

Drs. Paul Strassburger, C. Zent Garber and Halford Hallock, New York, presented a paper on "Fibrous Dysplasia of Bone." Discussed by Drs. C. Glenn Barber, Cleveland; Douglas H. Collins, Leeds, England, and Paul Strassburger, New York.

Drs. Charles F. Geschickter and Murray M. Copeland, Washington, D. C., presented a paper on "Parosteal Osteoma or Myo-Osseous Osteoma." Discussed by Drs. H. L. Jaffe, New York; Albert B. Ferguson, Boston; H. R. McCarroll, St. Louis, and Charles F. Geschickter, Washington, D. C.

Dr. Allen S. Lloyd, Washington, D. C., read a paper on "Irritation of the Tibial and Peroneal Nerves as an Unrecognized Cause of Knee Pain." Discussed by Drs. I. W. Nachlas, Baltimore; Julius S. Neviaser, Washington, D. C., and Allen S. Lloyd, Washington, D. C.

Dr. Edwin David Weinberg, Baltimore, read a paper on "The Spontaneous Rupture of the Extensor Pollicis Longus Tendon Following Colles' Fracture." Discussed by Drs. Henry F. Ullrich, Baltimore; Herbert C. Fett, Brooklyn, and Edwin David Weinberg, Baltimore.

### Thursday, June 9—Morning

The following officers were elected: chairman, Dr. Joseph S. Barr, Boston; vice chairman, Dr. Walter P. Blount, Milwaukee; secretary, Dr. Charles N. Pease; for nomination to the American Board of Orthopedic Surgery, Dr. William T. Green, Boston, and Dr. Carl E. Badgley, Ann Arbor.

On motion duly made and seconded, it was voted that a committee be appointed to make suggestions to the American Medical Association for revision of the rules of the section and report at the next meeting. The committee thus appointed consisted of Edward L. Compere, Chicago; William Tobin, Washington, D. C., and Paul C. Colonna, Philadelphia.

Dr. Dana M. Street, Memphis, Tenn., read a paper on "Medullary Nailing: A Comparative Study of Skeletal Traction, Dual Plating and Medullary Nailing." Discussed by Drs. G. O. Eaton, Baltimore; Leslie V. Rush, Meridian, Miss.; J. Warren White, Greenville, S. C., and Dana M. Street, Memphis, Tenn.

Dr. David M. Bosworth, New York, read the chairman's address, entitled "Blade Plate Fixation for Fractures of the Surgical Neck of the Humerus and Similar Lesions."

Drs. J. G. Petrie and William V. Cone, Montreal, Canada, presented a paper on "The Treatment of Fracture Dislocation of the Spine by Open Reduction and Internal Fixation." Discussed by Drs. E. F. Cave, Boston; Frank E. Stinchfield, New York, and J. G. Petrie, Montreal.

Dr. Frederick M. Smith, New York, read a paper on "Injuries of the Medial Epicondyle of the Humerus." Discussed by Drs. Leonard T. Peterson, Washington, D. C.; Maurice M. Pile, Hartford, Conn.; Walter P. Blount, Milwaukee; Harold R. Bowman, Baltimore, and Frederick M. Smith, New York.

Dr. Albert B. Ferguson, Boston, read a paper on "Roentgenographic Union of Bone Fragments. Discussed by Drs. Lenox D. Baker, Durham, N. C.; Ralph S. Bromer, Bryn Mawr, Pa.; J. Warren White, Greenville, S. C., and Albert B. Ferguson, Boston.

### Friday, June 10—Morning

Dr. Robert Leland Maynard, Burlington, Vt., read a paper on "A Summary of the Ski Fractures in the Stowe, Vt., Area for the Past Five Years." Discussed by Drs. Kenneth Christophe, Brookline, Mass.; John Royal Moore, Philadelphia, and Dr. Robert Leland Maynard, Burlington, Vt.

Drs. Mark B. Coventry, John C. Ivins, L. A. Weed and D. R. Nichols, Rochester, Minn., presented a paper on "Infection of the Hip Joint by Brucella Suis." Discussed by Drs. R. Beverly Raney, Durham, N. C.; A. Bruce Gill, Philadelphia, and Mark B. Coventry, Rochester, Minn.

Dr. Jesse T. Nicholson, Philadelphia, read a paper on "Pyogenic Arthritis of the Hip in Infants." Discussed by Drs. Henry B. Crawford, Rochester, N. Y.; John A. Heberling, Pittsburgh; Joseph S. Barr, Boston; David M. Bosworth, New York; Whitfield Larrabee, Hartford, Conn.; Alan DeF. Smith, New York; Philip Lewin, Chicago; A. Bruce Gill, Philadelphia; Paul Hugenberger, Boston, and Jesse T. Nicholson, Philadelphia.

Drs. Edward L. Compere and William J. Schnute, Chicago, presented a paper on "Treatment of Congenital Dislocation of the Hip Without Open Surgery." Discussed by Drs. Walter P. Blount, Milwaukee; J. Warren White, Greenville, S. C.; G. DeN. Hough, Springfield, Mass.; Paul Colonna, Philadelphia; Vernon P. Hart, Minneapolis; A. Bruce Gill, Philadelphia; Oscar LeClercq, Brussels, Belgium, and Edward L. Compere, Chicago.

Drs. Donald W. McCormick and Walter P. Blount, Milwaukee, presented a paper on "Metatarsus Adductus More Prevalent Than Clubfoot." Discussed by Drs. Philip Lewin, Chicago; Charles W. Peabody, Detroit, and Walter P. Blount, Milwaukee.

Drs. Alan DeF. Smith and Horace I. Yu, New York, presented a paper on "Streptomycin Combined with Surgery in the Treatment of Bone and Joint Tuberculosis." Discussed by Drs. Charles N. Pease, Chicago; Paul W. Hugenberger, Boston; Timothy C. H. Liang, Cassadago, N. Y.; David M. Bosworth, New York, and Alan DeF. Smith, New York.

## SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

### Wednesday, June 8—Afternoon

The meeting was called to order at 2 p. m. by the chairman, Dr. William H. Daniel, Los Angeles.

Dr. Edwin Boros, New York, read a paper on "The Role of the Esophagus in Local and Systemic Disease." Discussed by Drs. Moses Paulson, Baltimore; Edward B. Benedict, Boston; John Tilden Howard, Baltimore; Philip Thorek, Chicago; Hyman I. Goldstein, Camden, and Edwin Boros, New York.

Drs. Samuel A. Wilkinson Jr. and Martin L. Tracey, Boston, presented a paper on "History of Hemorrhage in Ulcer." Discussed by Drs. Donovan C. Browne, New Orleans; Samuel Marshall, Boston; Meyer A. Rabinowitz, Brooklyn, and Samuel A. Wilkinson Jr., Boston.

Dr. Mandred W. Comfort, Rochester, Minn., read a paper on "Gastric Acidity Before and After Development of Gastric Cancer: Diagnostic and Prognostic Significance." Discussed by Drs. Leon Schiff, Cincinnati; Arthur J. Atkinson, Chicago; Frederick W. Mulsow, Cedar Rapids, Iowa; Hyman I. Goldstein, Camden, N. J.; Joseph B. Kirsner, Chicago, and Mandred W. Comfort, Rochester, Minn.

Drs. Otto C. Pickhardt and Henry A. Rafsky, New York, presented a paper on "The Treatment of Hiatus Hernia in Older People." Discussed by Drs. Irving B. Brick, Washington, D. C.; Herbert Caisle Maier, New York; Barney J. Dryfuss, New York; Henry A. Rafsky, New York, and Otto C. Pickhardt, New York.

Drs. Harry Shay, S. A. Komarov and J. Edward Berk, Philadelphia, presented a paper on "Some Fallacies in the Clinical Measurement of Gastric Acidity with Special Reference to the Histamine Test." Discussed by Drs. H. L. Bockus, Philadelphia; Franklin Hollander, New York, and Harry Shay, Philadelphia.

Drs. C. W. Wirts and M. H. F. Friedman, Philadelphia, presented a paper on "The Use of Orally Administered Intestinal Extracts in the Treatment of Peptic Ulcer." Discussed by Drs. David J. Sandweiss, Detroit; H. Marvin Pollard, Ann Arbor, Mich.; Z. T. Bercovitz, New York, and M. H. F. Friedman, Philadelphia.

Drs. Stanley O. Hoerr, William R. Bliss and James Kauffman, Columbus, Ohio, presented a paper on "A Clinical Evaluation of Various Tests for Occult Blood in the Feces." Discussed by Drs. J. Edward Berk, Philadelphia, and Stanley O. Hoerr, Columbus, Ohio.

Drs. Harold Lincoln Thompson and DeVere W. McGuffin, Los Angeles, presented a paper on "Melena," Discussed by Drs. Z. T. Bercovitz, New York; John E. Dunphy, Boston; H. Necheles, Chicago; DeVere W. McGuffin, Los Angeles, and Harold Lincoln Thompson.

Dr. John H. Fitzgibbon, Portland, Ore., read a paper on "The Diagnosis of Lesions Near the Cardia." Discussed by Drs. Russell S. Boles, Philadelphia; A. H. Aaron, Buffalo; Edwin Boros, New York, and John H. Fitzgibbon, Portland, Ore.

### THURSDAY, JUNE 9—2 P. M.

The following officers were elected: chairman, Dr. Russell S. Boles, Philadelphia; vice chairman, Dr. N. G. Runyeon, Reading, Pa.; secretary, Dr. Donovan C. Browne, New Orleans; delegate, Dr. Louis A. Brice, Rochester, Minn.; alternate delegate, Dr. Walter A. Jansler, Minneapolis; co-chairmen of Scientific Exhibits, Dr. Everett D. Kieffer, Boston, and Dr. J. P. Nesselrod, Evanston, Ill.

On motion regularly made and seconded, it was voted unanimously to accept the recommendation of the Advisory Board for Medical Specialties and of the directors of the American Board of Proctology concerning changes in the rules of the American Board of Proctology.

Dr. William H. Daniel, Los Angeles, read the chairman's address on "Obstructive Lesions of the Left Colon and Rectum."

Drs. Samuel McLanahan, Glenn P. Grove and Richard F. Kieffer Jr., Baltimore, presented a paper on "An Evaluation of Conservative Surgery for Certain Rectal Adenomas Showing Malignant Change." Discussed by Dr. Harvey B. Stone, Baltimore, and Dr. Martin S. Kleckner, Allentown, Pa.

Dr. J. M. Ravid, New York, presented a paper on "Diastasis and Diastatic Perforation of the Gastrointestinal Tract: A Clinical Pathologic and Experimental Study." Discussed by Drs. James P. Croce and Con Amore V. Burt, New York.

Drs. Michael H. Streicher and Morton I. Grossman, Chicago, presented a paper on "The Use of Duodenal Substance in the Treatment of Chronic Ulcerative Colitis." Discussed by Drs. Burrill B. Chrohn, New York; Joseph B. Kirsner, Chicago; B. F. Haskell, Philadelphia, and Everett D. Kiefer, Boston.

Drs. J. A. Bargen and William G. Sauer, Rochester, Minn., presented a paper on "The Association of Chronic Ulcerative Colitis and Carcinoma." Discussed by Drs. Frank Lahey, Boston; Joseph D. Kirsner, Chicago; Anthony Bassler, New York, and J. Arnold Bargen, Rochester, Minn.

Drs. W. W. Babcock and Harry E. Bacon, Philadelphia, presented a paper "An Appraisal of Over 1,000 Operations for Carcinoma of the Large Bowel, with Special Reference to Those Without Abdominal Colostomy." Discussed by Drs. Lawrence Abel, London, England, and Louis E. Moon, Omaha.

Drs. William J. Grace, Stewart G. Wolf Jr. and Harold Wolff, New York, presented a paper on "Changes in Human Colonic Functions During Various Emotions and Feeling States: An Experimental Study." Discussed by Drs. Thomas P. Almy, New York; Asher Winkelstein, New York, and Sidney Portis, Chicago.

Drs. William P. Chapman, Eirwyn N. Rowlands and Chester M. Jones, Boston, presented a paper on "Multiple Balloon Kymographic Recordings of the Comparative Action of Various Drugs on the Motility of the Upper Small Intestine in Man." Discussed by Dr. Franz J. Ingelfinger, Boston.

## SECTION ON RADIOLOGY

### WEDNESDAY, JUNE 8—AFTERNOON

The meeting was called to order at 2:15 p. m. by the chairman, Dr. Harry M. Weber, Rochester, Minn.

Dr. Harry M. Weber, Rochester, Minn., read a paper, "The Significance of the Intestinal Polypoid Lesion."

Drs. Irving B. Brick and Harold I. Amory, Washington, D. C., presented a paper, "Incidence of Hiatus Hernia in Patients without Symptoms." Discussed by Drs. L. G. Rigler, Minneapolis; R. R. Newell, San Francisco, and Irving B. Brick.

Dr. Gerhart S. Schwarz, Clifton Springs, N. Y., read a paper, "X-Ray Differentiation Between Benign and Malignant Gastric Lesions." Discussed by Drs. L. G. Rigler, Minneapolis; Reid R. Heffner, New Rochelle, N. Y.; R. R. Newell, San Francisco, and Gerhart S. Schwarz.

Dr. Philip J. Hodes, Philadelphia, read a paper, "Roentgen Manifestations of Small Intestinal Bleeding." Discussed by Drs. Arthur Finkelstein, Jonathan Rhoads, and Philip J. Hodes, Philadelphia.

Drs. John F. Roach, Robert D. Sloan and Russell H. Morgan, Baltimore, presented a paper, "Photofluorography in the Early Detection of Gastric Malignancy." Discussed by Drs. Paul C. Hodges, Chicago; Moses Paulson, Baltimore; L. G. Rigler, Minneapolis, and John F. Roach.

Dr. Frank S. Windholz, San Francisco, presented a paper "Fractional Air Contrast: Barium Enema for Demonstration of Lesions in the Lower Sigmoid." Discussed by Drs. Harry M. Weber, Rochester, Minn.; R. R. Newell, San Francisco, and Frank S. Windholz.

### THURSDAY, JUNE 9—AFTERNOON

The meeting was called to order at 2:15 p. m. by the chairman, Dr. Harry M. Weber, Rochester, Minn.

It was moved and carried that the minutes of the last meeting, as published in THE JOURNAL, be officially adopted.

Dr. Sydney J. Hawley, Seattle, secretary of the Pacific Northwest Radiological Society, forwarded a communication incorporating a resolution, to the effect that the Pacific Northwest Radiological Society goes on record as most strongly opposing the proposed Blue Cross-Blue Shield, national health insurance plan, and requesting that word to that effect be transmitted to all the delegates of the American Medical Association and all the radiologic societies of the United States.

It was moved and carried that the secretary cast a unanimous ballot for the election of Dr. U. V. Portmann, Cleveland, as chairman, and Dr. J. C. Dickson, Tampa, Fla., as vice chairman of the Section on Radiology.

Dr. Fred J. Hodges, Ann Arbor, Mich., assumed the chairmanship.

Dr. Barton R. Young, Philadelphia, read a paper on "Important X-Ray Aspects of the Cranial Vault."

Dr. Merrill C. Sosman, Boston, read a paper on "Important X-Ray Aspects of Intracranial Structures."

Dr. Lewis E. Etter, Warrendale, Pa., read a paper on "Cranial Fracture."

These three papers were discussed by Drs. Donald D. Matson, Boston; John F. Holt, Ann Arbor, Mich.; A. W. Marcovich, Dayton, Ohio; Rudolph Jaeger, Philadelphia; Frank Windholz, San Francisco; Merrill C. Sosman, Boston, and Lewis E. Etter, Warrendale, Pa.

Dr. Robert P. Barden, Philadelphia, read a paper on "Encephalography."

Dr. Fred J. Hodges, Ann Arbor, Mich., read a paper on "Ventriculography."

Dr. C. R. Perryman, Baton Rouge, La., read a paper on "Cerebral Angiography."

These three papers were discussed by Drs. Robert C. Bassett, Ann Arbor, Mich.; J. A. Campbell, Indianapolis; John W. Turner, Springfield, Mass., and Fred J. Hodges, Ann Arbor, Mich.

### Friday, June 10—Afternoon

Drs. Wendell G. Scott and Sherwood Moore, St. Louis, presented a paper on "Advances in Cardiovascular Angiography and Aortography as Applied to the Diagnosis of Congenital Heart Disease." Discussed by Drs. Russell H. Morgan, Baltimore; Fred J. Hodges, Ann Arbor, and Wendell G. Scott, St. Louis.

Drs. Jack Lasner, Claude Snead and E. L. Jenkinson, Chicago, presented a paper on "Roentgen Therapy of Thrombophlebitis." Discussed by Dr. Geza de Takats, Chicago.

Drs. George S. Sharp and Herbert F. Williams, Pasadena, Calif., presented a paper on "Irradiation as the Preferred Treatment for Cancer of the Lip.". Discussed by Drs. Charles Martin, Dallas, Texas, and George S. Sharp, Pasadena.

Dr. Max Cutler, Chicago, read a paper on "The Treatment of Early Cancer of the Larynx." Discussed by Drs. John V. Blady, Philadelphia; H. B. Phillips, New York; Theodore P. Eberhard, Philadelphia; Maurice Lenz, New York, and Max Cutler, Chicago.

Dr. H. Marks, New York, read a paper on "Clinical Experience with Irradiation Through a Grid." Discussed by Drs. Maurice Lenz, New York; David E. Ehrlich, Brooklyn, and H. Marks, New York.

Dr. Anna Goldfeder, New York, read a paper on "Relative Radiosensitivities of Analogous Mammary Tumors." Discussed by Drs. Maurice Lenz, New York; Frederick P. Ellinger, Bethesda, Md., and Anna Goldfeder, New York.

The meeting adjourned at 4:40 p. m.

## SECTION ON ANESTHESIOLOGY

### Wednesday, June 8—Morning

The section was called to order at 9:15 a. m. by the chairman, Dr. C. Walter Metz, Denver.

Dr. H. S. Ruth, Haverford, Pa., section delegate to House of Delegates, gave the following report:

Mr. Chairman, Members of the Section, Guests: I shall confine my brief remarks to those matters which I believe to be of the greatest interest to the members of this section. There are, essentially, two items. The first has to do with the new code of ethics which was presented by the Judicial Council to the House on Monday, and which was passed with a change of only one word, from the form in which it was originally presented.

In the new code of ethics I believe there are two sections, as you will receive it later, and which will be of interest to you, and possibly helpful to you. The first section states briefly, "A physician should not dispose of his services under conditions that make it impossible to render adequate service to his patients, with the exception of an emergency."

The second section is very similar to a portion of the original code of ethics as reported for a number of years, with the addition of the word "hospital." "A physician should not dispose of his professional attainments or services to any hospital . . ." and then the other portions which have been in there ". . . under terms or conditions which permit exploitation of the services of the physician for the financial profit of the agency concerned."

The second item of interest to you, I believe, is the report of the so-called Hess Committee, which is the committee on hospitals and the practice of medicine. We believe that, essentially, this should be directed toward one of our great problems in the specialty.

The Hess Committee's recommendations have been prepared in mimeographed form and referred to the reference committee, which is studying it. They will report back to the House tomorrow.

We made two appearances yesterday in reference to the Hess Report, and I should like to thank those members of our section who were sufficiently interested to appear with us. In addition, we had the cooperation of two or three other sections specialties. This discussion will be continued before the reference committee at 10 a. m.

From our activities we hope to bring back certain amendments and changes to be submitted to the reference committee, so that the reference committee will recommend these changes to the House of Delegates tomorrow morning. We think that these changes will further strengthen the report and make the directives in the report more workable for our specialty.

I will not take up any more of your time at the moment, but until approximately 9:30 a. m. I will be in the room and I will be happy to answer any questions that any of you might have on the work of the House of Delegates in respect to the Section on Anesthesiology.

Dr. C. Walter Metz, Denver, reported that the request for the appropriation to conduct a survey of operating room deaths was disallowed.

Dr. Charles D. Anderson, Chicago, presented the following resolution:

Whereas, The House of Delegates previously approved the formation of study commissions in county and state Medical Societies, but no model exists except one in Philadelphia and perhaps one elsewhere, therefore be it

*Resolved*, That the Section on Anesthesiology request the House of Delegates to appropriate $450 for the printing of forms, for postage and so on, for the purpose of making a study to report deaths in operating rooms.

The motion was seconded by Dr. Paul Wood, New York, was put to a vote and was carried.

Dr. Charles D. Anderson, Chicago, read a paper on "Pentothal®-Curare Anesthesia in Upper Abdominal Surgery."

Drs. V. K. Stoelting and J. P. Graf, Indianapolis, presented a paper on "Dimethyl Ether of d-Tubocurarine Iodide as an Adjunct to Anesthesia."

Drs. H. J. Daly and S. V. Marshall, Sydney, Australia, presented a paper on "Experience with Relaxants during Anesthesia in Australia."

Dr. Geoffrey Organe, London, England, read his paper on "The Use in Anesthesia of a New Synthetic Curarizing Agent."

Drs. Harold R. Griffith, Montreal, Canada; Stuart C. Cullen, Iowa City; W. D. M. Paton, London, England; K. K. Chen, Indianapolis; Charles D. Anderson, Chicago; J. P. Graf, Indianapolis; H. J. Daly, Sydney, Australia, and Geoffrey Organe, London, England, discussed these papers.

Drs. Ivan B. Taylor, Gerald Edmonds and Walter H. Comer, Detroit, presented a paper, "Intravenous Procaine Hydrochloride During General Anesthesia."

Drs. Harold E. Godman and John Adriani, New Orleans, presented a paper, "Some Clinical Experiences with Various Muscle Relaxing Agents in the Management of Patients with Tetanus."

Drs. David J. Graubard, New York, and Milton C. Peterson, Kansas City, Mo., presented a paper, "The Use of Intravenous Procaine in the Management of Arthritis."

Drs. Julia G. Arrowood, Boston; Stevens J. Martin, Hartford, Conn.; George J. Boines, Wilmington, Del.; Norbert M. Bittrich, Detroit; Ivan B. Taylor, Detroit; F. F. Foldes, Pittsburgh; Harold E. Godman, New Orleans, and David J. Graubard, New York, discussed these papers.

### Thursday, June 9—Morning

The meeting was called to order at 9:10 a. m. by the chairman, Dr. C. Walter Metz, Denver.

Dr. C. Walter Metz, Denver, read letter from Dr. Harold Bishop, Valhalla, N. Y., requesting that his name not be considered for reappointment as representative of the Scientific Exhibit.

Dr. John S. Lundy, Rochester, Minn., read letter of thanks sent to Dr. Harold Bishop, Valhalla, N. Y., for past services.

Dr. Scott M. Smith, Salt Lake City, was elected to fill the post vacated by Dr. Harold Bishop, Valhalla, N. Y., as representative of Scientific Exhibits.

Dr. C. Walter Metz, Denver, read By-Laws pertaining to eligibility for voting, and appointed Drs. Lewis H. Wright, Great Neck, N. Y.; R. S. McKee, Leavenworth, Kan., and R. J. Whitacre, Cleveland, as tellers.

Since the terms of Drs. John S. Lundy, Rochester, Minn., and Henry S. Ruth, Haverford, Pa., were expiring, the following members were elected from the floor, their names to go for nomination to the American Board of Anesthesiology: for Dr. John S. Lundy's, Rochester, Minn., vacancy; Dr. Stuart C. Cullen, Iowa City; Dr. Ivan B. Taylor, Detroit, and Dr. Perry P. Volpitto, Augusta, Ga.; for Dr. Henry S. Ruth's, Haverford, Pa., vacancy, Dr. Robert Patterson, Pittsburgh; Dr. Stevens J. Martin, Hartford, Conn., and Dr. Scott M. Smith, Salt Lake City.

Dr. John S. Lundy, Rochester, Minn., was elected secretary for a term of three years.

Dr. Scott M. Smith, Salt Lake City, was elected vice chairman for a term of one year.

Dr. Fred Clement, Toledo, Ohio, was elected chairman for a term of one year.

Commander James G. Kurfees, Lieutenant Scott Whitehouse, and Lieutenant Frank Cerzosimo, U. S. Navy Medical Corps, presented a paper on "Anesthesia for the Paraplegic." Discussed by Drs. Lewis H. Wright, Great Neck, N. Y., and Dwight D. Grove, Philadelphia.

Drs. Perry P. Volpitto and John M. Brown, Augusta, Ga., presented a paper on "The Choice of Anesthesia in Patients with Emphysema." Discussed by Drs. Irving R. Hayman, Paterson, N. J.; R. Douglas Sanders, Wilmington, Del., and Perry P. Volpitto, Augusta, Ga.

Major Walter L. Lumpkin and Colonel James H. Forsee, U. S. Army Medical Corps, presented a paper on "The Use of Sodium Pentothal® and Local Procaine Anesthesia in Extrapleural Thoracoplasty in the Treatment of Pulmonary Tuberculosis." Discussed by Lieutenant Colonel Charles H. Mitchell, U. S. Army Medical Corps; Dr. M. Gene Black, Holyoke, Mass., and Major Walter L. Lumpkin, U. S. Army Medical Corps.

Dr. C. Walter Metz, Denver, presented a paper on "Anesthesia, Past and Present," which was the chairman's address.

Drs. Clarence L. Hebert, Staten Island, N. Y.; Carl E. Tetirick, Columbus, Ohio, and Joseph F. Ziemba, Staten Island, N. Y., presented a paper on "Complications of Spinal Anesthesia: An Evaluation of Complications Encountered in 7,000 Patients." Discussed by Lieutenant Colonel John Gardiner, U. S. Army Medical Corps; Drs. Meyer Saklad, Providence, R. I.; Foster Kennedy, New York; Allen Conroy, Chicago; Irving R. Hayman, Paterson, N. J.; Katzman, Washington, D. C.; Ernest A. Doud, San Diego, and Carl E. Tetirick, Columbus, Ohio.

Dr. Foster Kennedy, New York, requested an opportunity to speak twice. A vote was taken from the floor and, the members not being unanimously in favor of it, his request was denied.

Dr. Thomas H. Seldon, Rochester, Minn., presented a paper on "Supportive Therapy During Anesthesia and Operation." Discussed by Drs. Donald E. Hale, Cleveland; F. Woodbridge, Reading, Pa.; P. Lief, Denver, and Thomas H. Seldon, Rochester, Minn.

## JOINT MEETING ON SECTIONS OF ANESTHESIOLOGY AND SURGERY, GENERAL AND ABDOMINAL

FRIDAY, JUNE 10—MORNING

The meeting was called to order at 9:10 a. m. by the chairman, Dr. C. Walter Metz, Denver.

In the unavoidable absence of Dr. Frederick P. Haugen, Portland, Ore., Dr. Henry S. Ruth, Haverford, Pa., presented Dr. Haugen's paper on "Report of the Committee on Operative Mortality." Discussed by Drs. Roland Whitacre, Cleveland; Ambrose H. Storck, New Orleans; Geoffrey Organe, London, England, and Dr. Henry S. Ruth, Haverford, Pa.

Drs. F. A. Duncan Alexander and Carroll E. Kern, McKinney, Texas, and T. McD. Anderson, Dallas, Texas, presented a paper on "Management of Pain." Discussed by Drs. Henry S. Ruth, Haverford, Pa.; Sedgwick Mead, St. Louis; Robert A. Ravich, Brooklyn, and F. A. Duncan Alexander, McKinney, Texas.

Dr. Lloyd H. Mousel, Washington, D. C., read a paper on "Cyclopropane Anesthesia." Discussed by Drs. Robert D. Dripps, Philadelphia; Frank B. Berry, New York, and Lloyd H. Mousel, Washington, D. C.

Dr. William F. MacFee, New York, assumed the chairmanship.

Dr. Claude S. Beck and Mr. H. J. Rand III, Cleveland, presented a paper and motion film on "Cardiac Arrest During Anesthesia and Surgery." Discussed by Drs. Thomas J. Dry, Rochester, Minn.; Robert B. Orr, Lahey Clinic, Boston; John W. Devine Jr., Lynchburg, Va.; H. A. Gamble, Greenville, Miss., and S. L. Lieberman, Buffalo, and Mr. H. J. Rand III, Cleveland.

Dr. John C. Jones, Los Angeles, read a paper on "Anesthesia in Thoracic Surgery." Discussed by Drs. Charles F. McCuskey, Los Angeles; William Neff, San Francisco, and John C. Jones, Los Angeles.

Dr. C. R. Stephen, Montreal, Canada, read a paper on "Anesthesia in Infants and Young Children for Major Surgical Procedures." Discussed by Drs. Curtiss B. Hickcox, Hartford, Conn., and C. R. Stephen, Montreal, Canada.

## SECTION ON GENERAL PRACTICE

WEDNESDAY, JUNE 8, 1949

The meeting was called to order at 9 a. m. by the chairman, Dr. Winfred B. Harm, Detroit.

Dr. Winfred B. Harm, Detroit, read the chairman's address entitled, "The Place of the General Practitioner in the Cancer Problem."

Dr. David I. Rutledge, Boston, read a paper on "Approach to the Diagnosis of Common Types of Congenital Heart Disase." Discussed by Drs. Allan L. Friedlich, Baltimore; Hyman I. Goldstein, Camden, N. J., and David I. Rutledge, Boston.

Dr. Cyrus C. Sturgis, Ann Arbor, Mich., read a paper on "Recent Advances in the Treatment of Hematologic Disorders." Discussed by Drs. Robert A. Hettig, Houston, Texas; S. M. Goldhamer, Cleveland, and Cyrus C. Sturgis, Ann Arbor, Mich.

Drs. Arthur M. Master, Simon Dack, Leonard Field and Henry Horn, New York, presented a paper on "Diagnosis and Treatment of Acute Coronary Diseases." Discussed by Drs. B. S. Oppenheimer, New York; Hyman I. Goldstein, Camden, N. J., and Arthur M. Master, New York.

Dr. Egmont J. Orbach, New Britain, Conn., read a paper on "Contributions to the Therapy of the Varicose Complex." Discussed by Drs. William M. Cooper, New York; L. Reiner, Belleville, N. J., and Egmont J. Orbach, New Britain, Conn.

Dr. Edward Scott O'Keefe, Lynn, Mass., read a paper on "A High Calory Diet in the Treatment of Diarrhea in Infancy." A number of written questions were handed in and discussed by Dr. O'Keefe.

Dr. Fred W. Wittich, Minneapolis, read a paper on "The Treatment of Allergies as Seen in General Practice." Discussed by Drs. Harold A. Abramson, New York; George E. Rockwell, Milford, Ohio; Myer Solis-Cohen, Philadelphia, and Fred W. Wittich, Minneapolis.

THURSDAY, JUNE 9, 1949

### *Executive Session*

Dr. Paul Davis, delegate to the House of Delegates, gave a brief report of the meeting of the House of Delegates with reference to matters of interest to general practitioners, reporting, in particular, that the Committee to Study the Conditions of General Practitioners had been reactivated.

The following officers were elected: chairman, Dr. Milton B. Casebolt, Kansas City, Mo.; vice chairman, Dr. Lester Bibler, Indianapolis, and secretary, Dr. Thomas E. Robinson, Salt Lake City.

Dr. Richard Mills, Florida, was appointed as the section's representative to the Scientific Exhibits Section.

### *Scientific Session*

Dr. Augustus M. Davison, Hot Springs National Park, Ark., read a paper on "Diagnosis of Osteoarthritis." Discussed by Drs. Charles J. Smyth, Eloise, Mich., and Joseph L. Hollander, Philadelphia.

Drs. Chester H. Adams and Russell L. Cecil, New York, presented a paper on "Results of Gold Therapy in Early Cases of Rheumatoid Arthritis." Discussed by Drs. Ralph H. Boots, New York; William D. Robinson, Ann Arbor, Mich., and Russell L. Cecil, New York.

Dr. Currier McEwen, New York, read a paper on "Diagnosis and Treatment of Rheumatic Rever." Discussed by Drs. Benedict F. Massell, Boston; Eric Bywater, London, England; P. S. Hench, Rochester, Minn., and Currier McEwen, New York.

Dr. George S. Phalen, Cleveland, read a paper on "Diagnosis and Treatment of Mechanical Bachache; the Most Common Type of Low Back Pain." Discussed by Drs. H. Worley Kendall, Chicago; Theodore Potter, Boston, and Janet Travell, New York.

Dr. Ralph L. Gorrell, Clarion, Iowa, read a paper on "The Injection of Analgesic Drugs in the Treatment of Musculofascial Pain." Discussed by Drs. Janet Travell, New York, and Ralph L. Gorrell, Clarion, Iowa.

### Friday, June 10, 1949

Dr. Edward F. McLaughlin, Philadelphia, read a paper on "Hernia in General Practice."

Dr. Reed S. Clegg, Salt Lake City, read a paper on "Newer Concepts of Recognition and Prevention of Congenital Dislocations of the Hip." Discussed by Drs. Vernon Hart, Minneapolis, and Reed S. Clegg, Salt Lake City.

Dr. Fred W. Rankin, Lexington, Ky., read a paper on "The Diagnosis and Treatment of Cancer of the Lower Gastrointestinal Tract." Discussed by Drs. T. E. Jones, Cleveland; R. K. Gilchrist, Chicago, and Fred W. Rankin, Lexington, Ky.

Dr. William C. Roberts, Panama City, Fla., presented a moving picture, "War Surgery: Motion Picture in Color of Front Line Surgery."

Dr. Philip Thorek, Chicago, read a paper on "Jaundice." Discussed by Drs. Elmer C. Texter, Detroit; R. B. Robins, Camden, Ark.; Najib-Farah, Alexandria, Egypt, and Philip Thorek, Chicago.

Dr. Alton Ochsner, New Orleans, read a paper on "Intrathoracic Neoplasia." Discussed by Dr. William F. Rienhoff, Baltimore.

## SECTION ON DISEASES OF THE CHEST

### Wednesday, June 8, 1949

The meeting was called to order at 2:05 p. m. by the chairman, Dr. S. U. Marietta, Washington, D. C.

Dr. S. U. Marietta, Washington, D. C., read the chairman's address.

Drs. H. McLeod Riggins, Harry A. Bray, Ralph Horton, N. Stanley Lincoln and Arthur M. Stokes, New York, presented a paper on "Streptomycin and Dihydrostreptomycin in the Treatment of Tuberculosis." Discussed by Drs. Robert E. Plunkett, Albany, N. Y.; S. A. Waksman, New Brunswick, N. J.; Mourse J. Romansky, Washington, D. C., and H. McLeod Riggins, New York.

Dr. Arthur J. Vorwald, Saranac Lake, N. Y., read a paper on "Individual Variations in the Pulmonary Reaction to Dust." Discussed by Dr. Oscar A. Sander, Milwaukee.

Dr. Edgar M. Medlar, Sunmount, N. Y., read a paper on "What Can Prophylactic Vaccination (BCG) Against Tuberculosis Contribute to the Control of This Disease?" Discussed by Dr. Robert J. Anderson, Washington, D. C., and Dr. Henry C. Sweany, Chicago.

Drs. Herman J. Moersch and John R. McDonald, Rochester, Minn., presented a paper on "Bronchial Adenoma." Discussed by Drs. Porter P. Vinson, Richmond, Va.; Seymour R. Farber, San Francisco (discussion read by Dr. J. Winthrop Peabody, Washington, D. C.); Alfred Goldman, Beverly Hills, Calif., and Herman J. Moersch, Rochester, Minn.

### Thursday, June 9, 1949

### *Executive Session*

The following officers were elected: chairman, Dr. Walter E. Vest, Huntington, W. Va.; vice chairman, Dr. Alvis E. Greer, Houston, Texas; secretary, for three year period, Dr. Jay A. Myers, Minneapolis, Minn.; delegate, Dr. Hollis E. Johnson, Nashville, Tenn.; alternate, Dr. Karl H. Pfentze, Cannon Falls, Minn.

### *Scientific Session*

Dr. Leo G. Rigler, Minneapolis, read a paper on "Limitations of X-Ray Examination in the Diagnosis of Diseases of the Chest." Discussed by Drs. Lawrence L. Robbins, Boston; Philip J. Hodes, Philadelphia; and Leo G. Rigler, Minneapolis.

Dr. Edgar Mayer, New York, read a paper on "Pulmonary Emphysema." Discussed by Drs. Alvan L. Barach, New York, and Maurice S. Segal, Boston.

Dr. Richard H. Overholt, Brookline, Mass., read a paper on "The Silent Phase of Lung Cancer." Discussed by Drs. John E. Dunn, Washington, D. C.; Otto C. Brantigan, Baltimore; Leo G. Rigler, Minneapolis, and Richard H. Overholt, Brookline, Mass.

Drs. David A. Cooper and Katharine R. Boucot, Philadelphia, presented a paper on "A Critical Evaluation of Mass X-Ray Surveys." Discussed by Drs. William Roemmich, Baltimore, and Herman E. Hilleboe, Albany, N. Y.

Dr. David T. Smith, Durham, N. C., read a paper on "Pulmonary Mycosis." Discussed by Dr. Chris J. D. Zarafonetis, Ann Arbor, Mich.

## SECTION ON MISCELLANEOUS TOPICS

### *Session on Physical Medicine and Rehabilitation*

### Wednesday, June 8, 1949

The meeting was called to order at 9 a. m. by the chairman, Dr. Howard A. Rusk, New York.

Dr. Svend Clemmesen, Copenhagen, Denmark, presented a paper on "The Principles of Remedial Exercise."

Drs. Frank H. Krusen, Byron E. Hall and Henry W. Woltman, Rochester, Minn., presented a paper on "Coördination Exercises and Vitamin $B_{12}$ for Combined Degeneration of the Spinal Cord in Pernicious Anemia." Discussed by Drs. Gusta Davidsohn, Chicago, and Byron E. Hall, Rochester, Minn.

Drs. Samuel S. Sverdlik and Howard A. Rusk, New York, presented a paper on "The Rehabilitation of Quadriplegics." Discussed by Drs. Howard Rusk, New York; H. Worley Kendell, Chicago; Nicholas D. Mauriello, Wilkes-Barre, Pa.; H. Burt, London, England; F. M. Schwartz, Birmingham, Ala., and Samuel S. Sverdlik, New York.

Dr. Lewis B. Newman, Hines, Ill., read a paper on "Physical Medicine and Rehabilitation in the Veterans Administration." Discussed by Drs. A. B. C. Knudson, Washington, D. C.; William S. Tegner, London, England; Herbert Kent, New York; Nicholas D. Mauriello, Wilkes-Barre, Pa.; Howard A. Rusk, New York, and Lewis B. Newman, Hines, Ill.

The following papers were read as a panel discussion on "Certain Common Procedures in Physical Medicine and Rehabilitation":

Dr. George G. Deaver, New York: "What Every Physician Should Know About the Teaching of Crutch Walking."

Dr. Sidney Licht, Boston: "What Every Physician Should Know About Occupational Therapy."

Dr. Gordon M. Martin, Rochester, Minn.: "What Every Physician Should Know About Prescribing Physical Therapy."

Dr. George M. Piersol, Philadelphia: "What Every Physician Should Know About the Office Practice of Physical Medicine and Rehabilitation."

Dr. William D. Paul, Iowa City: "What Every Physician Should Know About the Hospital Practice of Physical Medicine and Rehabilitation."

Written questions were presented to the panel members through the moderator, Dr. Howard A. Rusk, New York.

THURSDAY, JUNE 9—MORNING

The meeting was called to order by the chairman, Dr. Howard A. Rusk, New York, at 9 a. m.

Dr. William S. C. Copeman, London, England, presented a paper on "Physical Medicine As Related to Rheumatic Diseases." Discussed by Dr. Frank H. Krusen, Rochester, Minn.

Drs. John S. Coulter, Howard A. Carter and Frederic T. Jung, Chicago, presented a paper on "What the Council on Physical Medicine and Rehabilitation Has to Offer the Physician."

Dr. William S. Tegner, London, England, presented a paper on "Physical Treatment of Common Lesions of the Shoulder." Discussed by Drs. Svend Clemmesen, Copenhagen, Denmark; Bror Troedsson, Orange, N. J.; Nicholas Mauriello, Wilkes-Barre, Pa.; G. Hirschberg, Bronx, N. Y., and Howard A. Rusk, New York.

Dr. William Bierman, New York, presented a paper on "Physical Medicine in Peripheral Vascular Diseases."

The following papers were read as a panel discussion on "Certain Common Indications for Physical Medicine and Rehabilitation."

Dr. Alfred R. Shands Jr., Wilmington, Del.: "What Every Physician Should Know About the Rehabilitation of the Crippled Child."

Dr. Hans Kraus, New York: "What Every Physician Should Know About the Physical Treatment of Backache."

Dr. F. A. Hellebrandt, Richmond, Va.: "What Every Physician Should Know About Physical Medicine and Rehabilitation in Prevention of Chronic Invalidism."

Dr. Robert C. Darling, New York: "What Every Physician Should Know About Physical Fitness."

Dr. Donald A. Covalt, New York: "What Every Physician Should Know About Physical Medicine and Rehabilitation for Industrial Injuries."

Written questions were presented to the panel members through the moderator, Dr. Howard A. Rusk, New York.

### *Session on Allergy*

FRIDAY, JUNE 10—MORNING

The meeting was called to order at 9:10 a. m. by the chairman of the session, Dr. Charles H. Evermann, St. Louis.

Dr. Bret Ratner, New York, read a paper on "Asthma in Children: Salient Diagnostic Problems." Discussed by Drs. James C. Overall, Nashville, Tenn.; Walter Finke, Rochester, N. Y.; Edward O'Keefe, Lynn, Mass., and Bret Ratner, New York.

Dr. Oscar Swineford Jr., Charlottesville, Va., presented a paper on "Observations on the Use of Bacterial Antigens in the Treatment of Asthma: A Brief Critical Review." Discussed by Drs. Frank Perlman, Portland, Ore.; Myer Solis-Cohen, Philadelphia; John Fromer, Boston, and Oscar Swineford Jr., Charlottesville, Va.

Dr. George Piness, Los Angeles, read a paper on "Status Asthmaticus." Discussed by Drs. Maurice S. Segal, Boston; Meyer A. Rabinowitz, Brooklyn; Bert Ratner, New York, and George Piness, Los Angeles.

Drs. Howard J. Lee and T. L. Squier, Milwaukee, presented a paper on "Provocative Diets in the Recognition of Food Allergy." Discussed by Drs. Hal McC. Davison, Atlanta, Ga.; Philip M. Gottlieb, Philadelphia, and Howard J. Lee, Milwaukee.

Dr. James R. Webster, Chicago, read a paper on "Dermatoses Which May Have an Allergic Etiology." Discussed by Drs. Nelson Paul Anderson, Los Angeles; Louis Tuft, Philadelphia; John Fromer, Boston, and James R. Webster, Chicago.

Dr. Walter L. Winkenwerder, Baltimore, read a paper on "The Clinical Indications and Limitations of the Antihistamine Drugs in Allergy." Discussed by Dr. Maurice S. Segal, Boston.

Dr. Charles H. Evermann, St. Louis, read the chairman's address, entitled "Clinical Experiences with the Diagnosis of Asthma."

# Hearings On Health Insurance

MAY 25, 1949

AFTERNOON SESSION—Continued

United States Senate, Subcommittee on Health of the Committee on Labor and Public Welfare

SENATOR JAMES E. MURRAY, presiding

Present: SENATORS MURRAY, TAFT and DONNELL

SENATOR PEPPER: I would like you to know, doctor, that I certainly recognize the right of every citizen to advocate any honorable course of action as the public policy of this country, and certainly no one has any right to condemn anybody who advocates what he honestly believes to be in the public interest if it meets reasonable standards of merit.

I subscribe to your hope that we may get away from the practice of name-calling. Would you go so far as to say that would prevent you folks who do not like our national health insurance program to quit calling us the advocates of socialized medicine?

DR. GOIN: Well, Senator, there we get into an exercise in semantics, just what socialized medicine is. It is a nice, convenient name, and people know what it means.

SENATOR PEPPER: The unfortunate connotation of it is that it suggests, and a lot of people charge, that anybody who advocates what they call socialized medicine is open to doubt as to whether they are good Americans or whether they are trying to import communism or something else into this country.

I think it would clarify the atmosphere a good deal if we could discuss this on the merits of it. As I said to a medical society in Jacksonville when I spoke to them, I will not accuse you of being selfish and acting out of pecuniary motives if you will not accuse me of being a socialist and acting out of sheer political merits.

Doctor, in your testimony, on the second page you referred there to the large "death rate from diphtheria per hundred thousand of population, in the last year for which comparative figures were available." It was "11.6 for Great Britain, 11.4 for Germany, but in the United States with a free enterprise system of medical care, it was less than 6.0. Why?" Now, what year did you have in mind there?

DR. GOIN: I believe the year 1939.

SENATOR PEPPER: Did they have compulsory health insurance which included the treatment for diphtheria in Germany for 1939?

DR. GOIN: They have had it since 1884.

SENATOR PEPPER: Did the health plan in effect in England in 1939 include treatment of diphtheria in children?

DR. GOIN: It included sicknesses of all insured persons.

SENATOR PEPPER: My advice is that it was only included in this system that went into effect last year in England. Now, 1946 is the year you used for comparison with respect to tuberculosis?

DR. GOIN: Not I; the Public Health Service.

SENATOR PEPPER: Well, "in the United States the rate was 47 per hundred thousand; in England and Wales it was 62; in France it was 137, and in Russia, 160." Of course, the year 1946, in respect to England, France and Russia, was pretty close after those countries had been through four years of war. Do you think that is a good year for comparison?

DR. GOIN: Perhaps not. It is the data I had available from Public Health Service.

SENATOR PEPPER: I do not think you would suggest that conditions were as severe in the United States as in those countries?

DR. GOIN: I would grant that.

SENATOR PEPPER: Now, you refer on page three to the death rate from communicable diseases. Would you say that the United States Public Health Service and the health services of the states and counties have had some influence in the reduction of that death rate?

DR. GOIN: I have no doubt about it.

SENATOR PEPPER: So all of that is not attributed to the private practice of medicine in the country?

DR. GOIN: No. The figure was quoted so triumphantly in Mr. Ewing's reports that I thought it might be well to debunk it slightly.

Senator Pepper: Under the voluntary plans, including the doctors' plans, can any patient get any service that he requests without having to have it approved by the doctor, if necessary?

Dr. Goin: No, I do not think any person could under any plan.

Senator Pepper: Well, somebody in respect to the Blue Cross and the other prepaid voluntary plans—does not somebody exercise some cautionary discretion?

Dr. Goin: I can only speak with authority for California Physicians' Service. No one can tell me not to have a roentgen study made if I am one of the subscribers.

Senator Pepper: Does every patient who wants a laboratory test and roentgen test, regardless of the doctor—

Dr. Goin: No, it is the doctor's opinion—but not some other doctor's.

Senator Pepper: Now, doctor, you said that medical care was only a small part of the medical problem, and you spoke about the value of good housing and school lunch programs and decent wages and adequate clothing. Because those do contribute to better health, has the American Medical Association made it a policy to support those measures when they have been before Congress?

Dr. Goin: I do not think it is a matter of concern with the American Medical Association. It is a matter of concern with every doctor as a citizen, but not a proper attitude for a medical association.

Senator Pepper: Although they would be in the interest of the better health of the people?

Dr. Goin: I think that is perhaps going a little too far. None of us have enough practical knowledge.

Senator Pepper: You were speaking awhile ago about the objective in the discussion of this matter, and I believe the first time you called the National Health Insurance Plan the national sickness plan in your statement. Are you now designating the National Health Insurance as the National Health-Sickness Plan?

Dr. Goin: Without the word health.

Senator Pepper: You do not mean we are trying to tax health?

Dr. Goin: I want to cease calling this health because I think it has little to do with health and nothing to do with insurance. It is certainly a tax provided for sickness, so I just like that name.

Senator Pepper: Well, have you any suggestion as to a name that we should apply and one that you should apply?

Dr. Goin: No, we have just one common name—sickness tax.

Senator Pepper: You would call it sickness tax? You think a bill that is designed to provide medical care for those who are sick should be called the sickness bill?

Dr. Goin: It seems to me like a good name.

Senator Pepper: And you do not think it is insurance?

Dr. Goin: Where you tax the people a part of their payroll or their income, no, I do not.

Senator Pepper: Doctor, you probably suggest that the treatment of disease and the care of patients who are ill is the prerogative of the skilled person; that is to say, the doctor, and that the layman should not interfere with the administration of medical care to the patient; that is correct, is it not?

Dr. Goin: I would believe that, yes.

Senator Pepper: Now, are doctors also specialists in economic matters? . . .

I was wondering whether or not the doctors were justified in going into the matter of how the people of the country could pay for the medical care they get; if the doctors were justified in denying the people the right to survey this field and to decide the best plan by which the people can pay the doctors for their services.

Dr. Goin: I do not believe they ever dreamed of denying that right. I think all that the doctors say is that they feel it is their duty to point out to the people and to those who make our laws that in our professional judgment this will not be a good way to serve the health of our people.

Senator Pepper: Now, doctor, as I understand, what we call the National Health Insurance Law is primarily a plan by which people are required to take out insurance; that is, to become members of the system by paying a part of their income periodically, and, as I understand, there is no compulsion on the patient with respect to the choice of doctor, or any compulsion on the doctor, either to come into the plan or with respect to the acceptance of the patient. It does contemplate, obviously, that there would probably be some agreement as to a scale of fees that the doctors might charge and that the hospitals might charge for medical services that might be rendered for the patients.

Dr. Goin: I understand that is proposed as one of the alternatives, but I do not think it will ever be done.

Senator Pepper: You mean that if the plan should be adopted there would be no agreement between the agency and the hospital—between the doctor and the hospital—as to what their charges would be?

Dr. Goin: No. On the contrary, the law provides that the board may make a price for hospital accommodations, and it does not say anything about the hospital agreeing to it. It just says that the board shall fix a price and that they will be based on the plan. What would happen to the majority of our private hospitals who do not have such accommodations?

Senator Pepper: It is probable that if the plan were adopted there would be some general agreement between the agency and doctors as to the fees they would render for covered patients.

Dr. Goin: That there will be a capitation fee set up. Every expert that you have had before this committee who is in favor of compulsory health insurance has testified that no manner but the capitation fee is practical administratively, and that a fee scale and a fee for service basis would wreck the whole plan. I do not think anything but a capitation plan would be adopted.

Senator Pepper: Does not the language of the law itself allow the county medical society—would you turn to the language of the law that pertains to the matter. It says there shall be a fee schedule.

Dr. Goin: But, as a matter of fact, that will not be practical and it will not be done.

Senator Pepper: What I am getting at is we have to concern ourselves with what the law says (page 118, Section 718):

> Agreements for the furnishing of medical or dental services (other than specialist services) as benefits under this title shall provide for payment—
> (1) on the basis of fees for services rendered as benefits, according to a fee schedule;
> (2) on a per capita basis, the amount being according to the number of individuals eligible for benefits who are on the practitioner's list;
> (3) on a salary basis, whole time or part time; or
> (4) on such combinations or modifications of these bases including separate provision for travel and related expenses, as may be approved by the State agency; according in each health-service area as the majority of the medical practitioners or of the dental practitioners, respectively, under agreement to furnish such services shall elect, et cetera.

Senator Taft, I am referring to page 118. The law gives the majority of the practitioners there the right to determine whether compensation shall be on a fee for service basis or one of these other methods.

Senator Pepper: What is the situation at the present time with respect to Blue Cross and the other prepayment plans? Is it some agreement as to a schedule of fees and hospital charges between the doctors and the hospitals and the authorities handling these plans?

Dr. Goin: There is an agreement between the hospitals and the Blue Cross. There is an agreement between the doctors and the Blue Shield, but they are agreements made between doctors—plans the doctors themselves have taken up.

Senator Pepper: The Blue Shield is simply a nonprofit organization; is it not?

Dr. Goin: Yes.

Senator Pepper: Is it operated by doctors or laymen?

Dr. Goin: I could not say. In our association of the voluntary medical care plan, it is operated by doctors. We have laymen on our board.

Senator Pepper: But is it your understanding that Blue Cross is operated by doctors or laymen?

Dr. Goin: Blue Cross is operated almost entirely by laymen.

Senator Pepper: Now, is there any agreement between Blue Cross representatives and hospitals as to what bills, what fees, the hospitals will charge covered patients for the services they render?

Dr. Goin: Surely.

Senator Pepper: That is an existing practice, is it?

Dr. Goin: Yes.

Senator Pepper: Currently carried on between the hospitals and the Blue Cross representatives, although Blue Cross representatives are generally laymen?

Dr. Goin: Yes.

Senator Pepper: Now, there is an agreed schedule of fees at present in practice in covered use between the doctors and Blue Shield, which is a voluntary association with respect to medical services, comparable to what Blue Cross is with the respective hospitals?

DR. GOIN: The Blue Shield is the name of an organization of medical care plans for the purpose of exchanging information and helping each other in general. The agreements are between the doctors and the various medical care plans and not really with Blue Shield.

SENATOR PEPPER: Yes, I know, but these Blue Shield—let us say that whatever the plans are at present, the voluntary plans under which you receive medical care on a prepayment basis, are these plans generally administered by laymen or doctors?

DR. GOIN: The executives are generally laymen.

SENATOR PEPPER: Now, these executives are the ones who enter into the agreement with respect to the schedule of fees by the doctors?

DR. GOIN: Not in our plan. California Physicians' Service, which is the second biggest plan. We set up the fee schedule.

SENATOR PEPPER: That is an association, however, set up by the doctors in California?

DR. GOIN: Yes.

SENATOR PEPPER: Not like these voluntary plans that are set up by laymen and not doctors?

DR. GOIN: Well, it is a voluntary plan. It just happens to be set up by doctors.

SENATOR PEPPER: What I am getting at is that a lot of doctors think it would be horrible to have any agreed scheduled fees between the agency, representing the National Health Insurance Program, and the doctors for the rendition of professional service. I was merely asking if that practice is not already prevalent in respect to the voluntary plans that are in existence.

Then I was next going to ask you, in the case of commercial insurance companies—doctors who practice, who render services to patients which are paid for by commercial companies—do they have any agreed schedule of fees for such companies?

DR. GOIN: I believe not. It is true in the voluntary plans in the Blue Shield organization, but I do not think it is with commercial carriers; nearly all of them indemnify. The doctor has no contractural relationship with them at all.

SENATOR PEPPER: They generally indemnify the patient that is covered. Is not that a principle that could be called a regulation here that might affect the doctor, simply to require him, if he comes into this system and renders medical care under the system, to agree with the agency with respect to schedule of fees generally, after the county medical society has determined what kind of payment shall be the custom?

DR. GOIN: I think that the doctor would feel better if it were indicated who would negotiate with him, and how. Primarily I do not think the doctor is concerned about his fee schedule and his fees; I think he is concerned about the federal degradation of the practice of medicine which he believes will follow the enactment of such law.

SENATOR PEPPER: Doctor, what is in this bill that suggests the degradation of the medical profession?

DR. GOIN: I do not think there is anything in the bill, but that is just the initial bill. There will be a series of directives and rules following this. Once you have committed yourself to it, you will not be able to back out.

SENATOR PEPPER: Do you not think Congress could reasonably be counted on to protect the medical profession from degradation, and to protect the people from that sort of distortion of the law?

DR. GOIN: So one might think the same thing of the House of Commons.

SENATOR PEPPER: It is difficult to make a comparison with another country. We get different advice as to how the system is working in England. I suppose you hear the doctors' side of it, and no doubt have the impression that it is not working out very well. Is that your impression?

DR. GOIN: It is indeed. My impression is that it gives extremely poor service. It is ruining doctors and discouraging their sons from becoming doctors.

SENATOR PEPPER: And that it is not in the public interest?

DR. GOIN: No.

SENATOR PEPPER: One other reference to England. I heard recently from a Labor member of the House of Commons and a Labor member of the House of Lords and from a Conservative of the House of Commons, who is not at all in sympathy with the Labor program—I heard all three of those men when they were visiting in Washington say, in effect, that the strongest appeal to the middle class, conservative, shopkeeping professional class of people was the existence of this health plan which the British Government now has in effect. . . . I do not know whether we would have similar experience if we had it in effect in this country; I would be willing to go to the people on the issue of whether or not it should be continued, if we could have an experiment with it.

DR. GOIN: Maybe we are confusing political value with medical value in this. I am not disputing political value.

SENATOR PEPPER: Doctor, you take the point of view that this legislation that some of us are sponsoring carries with it an implication that our medical care is not good and that our present system is bad in comparison with the systems of other countries. Of course, American medical care is the best in the world. But the question is: Is it as good as it could be in America?

DR. GOIN: I think not. . . . I will agree with you that we need to further our system of medical care. I do think we have a problem of medical care, but I do not think this is the way to solve it.

SENATOR DONNELL: Now, doctor, I want to ask you whether or not you believe this to be true: as you say in your statement here, "I oppose it as an American because I am persuaded that this type of legislation is one of the final steps on the road to state socialism." Is that your belief?

DR. GOIN: I do believe it.

SENATOR DONNELL: I have before me a copy of this 1679. On page 103, I call your attention to Title 7:

> The Congress hereby declares that it is the policy of the United States to take such steps and to utilize such of its resources as are necessary toward making adequate health services available to all our people regardless of residence, race, creed, color or economic status.

Do you agree with me that is a clear, definite statement of the fact that Congress declares that it is the policy of the United States to use the governmental resources in making available these health services?

DR. GOIN: It could not mean anything else.

SENATOR DONNELL: Is that one of the things that led you to think that this type of legislation is one of the final steps on the road to state socialism?

DR. GOIN: Yes, it is.

SENATOR DONNELL: Here is what occurs thereafter. On page 104 it starts out: "The personal health services to be made available as benefits to eligible individuals as provided in this part are medical services, dental services" under the terms of this bill, a government bill. Then I pass on to lines ten and eleven in reference to the persons who shall provide each respective class of service who are noted as: "who are qualified under part C of this title, to do so."

That indicates, does it not, that a law is entering into this in determining who shall be qualified to provide these services which are determined and defined to be benefits under this law of the United States?

DR. GOIN: True.

SENATOR DONNELL: Is not that a further indication as to whether or not this is on the road to state socialism?

DR. GOIN: I have no doubt of it.

SENATOR DONNELL: Now, doctor, look on the next page, if you will, on lines 13 and 14, the subject there under discussion is hospital services.

> Hospital services consist of hospitalization, including necessary nursing services, and such physician, laboratory, ambulance, and other services in connection with hospitalization as the National Health Insurance Board, after consultation with the National Advisory Medical Policy Council, by regulation designates as essential to good hospital care.

—those are two governmental boards; a board and a council created by this bill; are they not?

DR. GOIN: That is a point I tried to make. The language of the law is fairly gentle, but it is possible for the board to make any or almost any additional law that it so wishes.

SENATOR DONNELL: I just want to point out a few indications as to whether or not this is a governmental division, that it is something to be administered by the government, to be paid for by taxes secured by the government and under regulations under governmental boards.

This board and council to which reference is made on page 105 is a board and council, respectively, created by this bill, are they not?

DR. GOIN: Certainly.

SENATOR DONNELL: And the regulation referred to on page 103 and 104 is a governmental regulation, is it not?

Dr. Goin: Regulation of the board.

Senator Donnell: And it is a governmental board—the National Health Insurance Board?

Dr. Goin: Yes.

Senator Donnell: Now turn to page 136 of this bill and make a little inspection of what this National Health Insurance Board is.

In the first place, down at the bottom of the page 136, does it not read: "There is hereby established in the Federal Security Agency a National Health Insurance Board?"

Dr. Goin: Yes.

Senator Donnell: Mr. Oscar Ewing is to be the head?

Dr. Goin: Yes.

Senator Donnell: As the governmental security administrator? Now, this board is to be composed of five members, three of whom are to be appointed by the President and the other two of whom shall be the Surgeon General of the Public Health Service and the Commissioner for Social Security.

Dr. Goin: That would be the other two appointed by the President already.

Senator Donnell: The Surgeon General and the Commissioner for Social Security, of course. Then there are five appointees by the President. I would assume the Surgeon General and the Commissioner of Social Security are appointed by him; I have never heard anything to the contrary.

In the middle of the page, you will notice in lines eleven and twelve that "each appointed member shall receive a salary at the rate of $12,000 a year" with certain exceptions, for a term of six years. They are also forbidden to do anything else, so that board that is going to issue this regulation is to be a functioning governmental board, is it not?

Dr. Goin: Surely, full time.

Senator Donnell: Am I correct in assuming that to be one element which enters into whether or not this type of legislation is a step toward state socialism?

Dr. Goin: It seems so to me.

Senator Donnell: Now, if you will drop down to the bottom of page 137, I want to call your attention to this. Here we have a board, with power to make regulations, as specified on page 105, each member of which is to get $12,000 a year, and let us see what power that board has. On page 137, if you will be kind enough to refer to that: "all functions of the Board shall be administered by the Board," and what are the next words? "Under the direction and supervision of the Federal Security Administrator."

Dr. Goin: That is correct.

Senator Donnell: So we have a board here, a governmental board, paid good-sized salaries. All of these functions, which we read 32 pages ahead, are administered under the direction and supervision of the director.

Dr. Goin: When I read it it seemed to me that the functions remaining with the board were to do what the Administrator of the Federal Security Agency told them to do.

Senator Donnell: I do not think your conclusion is at all strange. At any rate, the language is as I read it, that all functions of the board shall be administered by the board under the direction and supervision of the Federal Security Administrator. It performs such "functions as it finds necessary to carry out the provisions of this title, and shall make all regulations and standards specifically authorized to be made in this title." You recognize those words: regulations and standards? It is going to have to make standards and regulations and such other regulations not inconsistent with this title as may be necessary. And then we read a little further on page 138:

> The Board may delegate to any of its members, officers or employees, or with the approval of the administrator to any other officer or employee of the Federal Security Agency, such of its powers or duties, except that of making regulations, as it may consider necessary and proper to carry out the provisions of this title.

Am I not correct in this analysis that back on page 105 is the power of making regulations, vested in this board, after consultation with the Advisory Council—all simmers down to the fact that all that making of regulations in the first place is to be done by a governmental organization, but is to be done under the direction and supervision of one individual, the Federal Security Administrator? And not only that regulation but all these regulations that are specified on page 138; namely, all regulations and standards specifically authorized to be made in this title, and such other regulations not inconsistent with this title as may be necessary; so I take it, doctor, that the power of regulations there is twofold: one, to make those it says you will and the others that he is told you cannot make; is that it? And that his whole power is subordinated to the one United States governmental official, namely, the Federal Security Administrator; is that correct?

Dr. Goin: That is correct.

Senator Donnell: Do you know if the Administrator shall ever have had any experience with the practice of medicine or health matters?

Dr. Goin: Nothing in here says so.

Senator Donnell: He is not a doctor, is he?

Dr. Goin: He is a lawyer.

Senator Donnell: Mr. Ewing came from New York City and is a lawyer.

Dr. Goin: That is my understanding.

Senator Donnell: If you just turn now to page 107, line 13, we will read a little more about what this board does:

> The Board shall have the duty of studying and making recommendations as to needed services and facilities for the care of the chronic sick afflicted with physical ailments, and for the care of individuals afflicted with mental or nervous diseases, and as to needed provisions for the prevention of chronic physical diseases and of mental or nervous diseases; and of making reports from time to time, with recommendations as to legislation, but the first such report shall be made not later than two years after benefits under this title first become available.

Doctor, would you not consider that a board that has the power of making recommendations as to the services for the care of the chronic sick and of the provisions for the prevention of chronic sickness, all this under the supervision and direction of the Federal Security Administrator, would you not consider that under those circumstances there is ample reason to say that this is a strong, a long step in the direction of state socialism?

Dr. Goin: I think it is, and I think it makes the Federal Security Administrator the director of medical care in America.

Senator Donnell: Now, Doctor, let us just turn to page 112. You will note at the bottom of the page, lines 22 and following:

> The Board,

—that is that same creature, the Board which is under the direction of the Federal Security Administrator—

> after consultation with the Advisory Council, shall establish standards as to the special skills and experience required to qualify an individual to render each such class of specialist services as benefits under this title, and to receive compensation for such specialist services. In establishing such standards and in determining whether individuals qualify thereunder, standards and certifications developed by professional agencies shall be utilized as far as is consistent with the purposes of this title, and regard shall be had for the varying needs and the available resources in professional personnel of the States and of local health-service areas.

That is a very important provision, is it not, Doctor, that the board, acting under the direction and supervision of the Federal Security Administrator, who is not a doctor and does not have to be a doctor, shall establish standards as to the special skills and experience required "to qualify an individual to render such class of specialist services as benefits under this title." That is an important, all-embracing power.

Dr. Goin: It frightened me when I read it because I have gone to the trouble of getting myself certificated by a professional examining board, and now Mr. Ewing, who does not, I imagine, take a very favorable view of me anyway, could easily uncertificate me.

Senator Donnell: It is rather curious that not only is this a governmental scheme worked out, to be administered by governmental officials, but a man who does not have to have studied medicine five minutes in his life has the power to direct a board as to the standards with respect to which the board fixes as to special skills and experience required to qualify a person to render specialist services. That is a pretty comprehensive power, to say the least.

Now would you turn to page 116, line 16, where it says: "Each agreement made under this part"—now, that part is Part C, which is "*Participation of Physicians, Dentists, Nurses, Hospitals, and Others.*" I call attention to the fact that among the agreements that are to be made under this part are the agreements set forth on page 118. Those are agreements for the furnishing of medical or dental services, other than specialist services, as benefits under this title, shall provide for payment—and then it tells the methods of payment. Here is an agreement for the furnishing of specialist services, and the agreements for the furnishing of hospital services, and so forth and so on, and with a provision down here on the agreement of furnishing hospital services that the board—the same board that is under the direction of the Administrator, after consultation with the Advisory Council and "with representatives of interested hospital organizations, may by regulation prescribe maximum rates for hospitalization furnished as benefits under this title."

Dr. Goin: If I were interested in setting up a truly socialistic system, that I could control, and if I were a social security administrator, I would fix the rates so low that the hospitals could not operate, and common sense and humanity would say that I would have to operate them.

Senator Donnell: There is no insurance against such a plan's being worked out under this bill, is there?

Dr. Goin: There is not.

Senator Donnell: There is an agreement on page 120, agreements for furnishing of home-nursing services or auxiliary services; there is a provision about the amount of payments for services—that is on page 120 and 121; all sorts of things are in here about the rates, and amounts of payments, and the assurance of "reasonable equivalent awards for practitioners selecting different methods of payment, in consideration of the value of the services they render."

There is a provision with respect to the maximum limits on the number of eligible persons with respect to whom any person may undertake to render services—all of these things on page 116.

Now, Doctor, do you agree that that says in effect that anybody who makes any of these agreements, that everybody who makes one of those contracts for any of these things agrees to comply with the regulations prescribed under this title?

Dr. Goin: You just have to sign a blank check.

Senator Donnell: You sign up to comply with [the regulations made by] this board that acts under the direction of the Federal Security Administrator and what he shall prescribe.

Now, let us take a glance at one or two other things. At the bottom of page 121 it says:

> Maximum limits upon the number of eligible individuals with respect to whom any person may undertake to render services in any local health service area may be fixed by the local administrative committee or local administrative officer of that health-service area only on the basis of a recommendation of the professional committee in that area that such limitation is necessary to maintain high standards in the quality of medical, dental, or other services furnished as benefits. Any such limits shall take account of professional needs and practices and shall provide suitable exceptions for emergency and temporary situations.

There it talks about local administrative committees.

This prescribes, does it not, quoting from the bottom of page 121, "Maximum limits upon the number of eligible individuals" may be prescribed, so that a doctor cannot take more than a certain number of persons, the maximum number of whom shall have been prescribed by this local administrative committee or local administrative officer.

Dr. Goin: Yes, that is one indication that the real intention is to function on a capitation basis. If you must have a maximum, you must have a capitation basis and a capitation panel.

Senator Donnell: Suppose you lived in Springfield, Ill., and Dr. Smith was the most popular doctor in Springfield, and they decide to follow this capitation plan, and Dr. Smith is allowed 1,000 patients. There is a great rush down to the post office on the day that the selection is to be made; everybody wants to take Dr. Smith and they can pick him and a thousand people take him right quickly. Then, Mr. Lawrence, over there, has been out of town for a few days. He has been living there in that town, and he wanted Dr. Smith, too. He is too late, and he has to take somebody else, unless there is some special provision made in this bill for Dr. Smith to have some elasticity in this list.

That makes it impossible for Dr. Smith to take on a dozen of us who happen to be out of town that day and cannot get in to make our selections. . . . Now, suppose I have selected Dr. Smith—I thought he was the very man, but suppose I am stricken with heart disease one year after that, and I think that Dr. Jones ought to have been the man whom I selected, but Dr. Jones' panel is full. Is there any hardship there that you see which is going to be inflicted on me?

Dr. Goin: I should think it is a very great one. You do not have a free choice of physicians at all, and furthermore if Dr. Jones' panel was not fully filled, you might find difficulty in transferring yourself from one panel to another.

Senator Donnell: In other words, you have to go through the forms and regulations, and whatever is prescribed here in order to get it done.

Dr. Goin: Yes, certainly.

Senator Donnell: Doctor, if you will now turn to—well, let us try page 143. It says:

> The Federal Security Administrator, through such units of the Federal Security Agency as he may determine, shall upon his own initiative or upon application of any individual make determinations as to the eligibility of individuals for benefits under this title.

Am I correct in my understanding, that that gives the Federal Security Administration the right to make a decision as to whether I am eligible for benefits under the title?

Dr. Goin: That is what it means.

Senator Donnell: There is some provision here about appeal. At any rate, in order to upset a decision made by the Federal Security Administrator in Washington, and acting through such unit of the Federal Security Agency as he may determine, you have to comply with whatever regulations have been prescribed by this board which the Federal Security Administrator himself directs.

Now, would you turn to page 134. Beginning with line 13 is a provision which is as follows:

> If a State has not prior to July 1, 1950, submitted and had approved a plan of operations, the Board shall notify the Governor of the State that the Board will be required to administer this title in the State, commencing July 1, 1951.

That is the federal board.

Dr. Goin: The state seems to have no choice at all.

Senator Donnell: In other words, the state has to submit a plan of operations. Now, if it has not done it by July 1, 1950, then the board, this federal board which is under the direction of Mr. Ewing, notifies the governor that the board will be required to administer the title in the state, commencing July 1, 1951.

Dr. Goin: The state has not only to submit the plan, but to have had it approved by the board. In other words, if the board does not like the plan the board can then go in and operate its own plan.

Senator Donnell: I am glad you called attention to it. Unless the board has decided in its wisdom, has put into its head, perhaps, by the Federal Security Administrator, who has this power of direction, if it has not approved the plan of operations by July 1, 1950, then the board can take charge and go ahead in the state.

Now, would you turn to the bottom of page 145. I was talking about these appeals of one kind or another. It tells all about what anybody can do if he is aggrieved. He may make a complaint to the local administrative officer or the local executive officer, that is, the person who is required to follow both the rules prescribed by the state and the rules prescribed by the board which, in turn, are subject to the administration of the Federal Security Administrator.

Here you are on your back with typhoid, and you do not like that; you have the privilege of making this complaint to this official.

If that officer to whom you have made that complaint finds, after investigation—he has the right to investigate; there is nothing prescribed there as to how long that investigation is required to be or how short it must be, is there?

Dr. Goin: He does not have to give him a complaint at all if he does not think it is well founded.

Senator Donnell: If the officer to whom such complaint is made finds, after investigation, that the complaint is well founded, he shall promptly take such steps as may be appropriate to correct the action or inaction complained of, and he shall notify the individual or other person making the complaint of his disposition thereof.

Now, suppose you are lying there sick, and he decides against you, and you think something ought to be done that is not done, and he investigates it, and you are getting sicker all the time, and he decides against you, but you have your rights all right. They are protected here in the next line.

Here you are now, suffering, and this says:

"Any such individual or other person dissatisfied"—you may not be conscious enough to know whether you were dissatisfied, but supposing you were. What do you do? You have got to do it in writing; I suppose typewriting would be sufficient, but it must be in writing, "request a hearing thereon and shall be afforded opportunity for the same pursuant to subsection (b), which says:

> *Provision* shall be made for the establishment of necessary and sufficient impartial tribunals to afford hearings to individuals and other persons entitled thereto under subsection (a) of this section, or section 717(d) of this title.

Well, let us turn back to 717(d)—that is where the state agency finds "that an individual or other person under agreement to furnish or provide personal health services as benefits is no longer qualified to furnish or provide such services, or has committed a substantial breach of the agreement," and so forth. Now, these tribunals are to be established to afford hearings under subsection (a) of this section, or back in section 717(d) of this title, and for further review of the findings, conclusions, and recommendations "of such tribunals, in accordance with regulations made by the Board, after consultation with the Advisory Council."

Of course, all the time the Federal Security Administrator is on top of the whole thing with his power of direction. It goes ahead here with further protective measures for you, who are lying there sick all the time. It says:

> With respect to any complaint involving matters or questions of professional practice or conduct

—you may have complained about the way the doctor acted toward you, his treatment—

> With respect to any complaint involving matters or questions of professional practice or conduct, the hearing body shall contain competent and disinterested professional representation; and with respect to any complaint *involving only matters or questions of professional practice or* conduct, the hearing body shall consist exclusively of such professional persons.

Now, Doctor, does that mean that you are going to have a jury of doctors which is going to pass on this thing? They have to be brought in to decide on that on appeal from the action of the local official; is that right?

Dr. Goin: I am sure that is the case.

Senator Donnell: Let us go on a little further. How are we going to pay for all this? You will notice on page 147 that there is created on the books of the Treasury a separate account to be known as the "Personal Health Services Account." Funds are to be invested by the Secretary of the Treasury. They are to be available for all expenditures, and there is going to be appropriated, first, "sums equal to 3 per centum of all wages estimated to be received during such fiscal year."

By the way, this does not provide anything for the fellow not getting wages. The indigent is not covered, is he?

Dr. Goin: Neither the indigent nor the person who has become too old to work.

Senator Donnell: Just the fellow who is fortunate enough to have a job is covered by S. 1679.

Dr. Goin: He has to have a job and a pay check.

Senator Donnell: Bearing all these things in mind, all this creation of boards and officials and rules and regulations and the Federal Security Administrator in Washington, D. C., sitting at the top of the heap, with the power of direction over the board that administers the whole thing, is there any doubt in your mind that that is a step on the road toward state socialism?

Dr. Goin: It is one of the last steps. I think we are almost there, if we do it.

Senator Donnell: Now, Doctor, I suppose that if there was a statute passed whereby everybody was to get $5 on every Monday morning, there would be many people to vote for persons who wanted to run for Congress on that plank, would you not think so?

Dr. Goin: I am sure that would be so.

Senator Donnell: If they actually got it started, a good many Congressmen would be afraid to change around after it once started.

Were you over in Germany?

Dr. Goin: I spent nine months doing graduate work at the University of Frankfurt, and observing this *Krankenkasse.*

Senator Donnell: Doctor, would you tell us what you would say with reference to the operation of the system they had in effect with respect to medical matters?

Dr. Goin: All of the German doctors I knew had from forty to sixty house calls to make every day. They had to travel all over the city, and in addition to that they had to see 25 to 40 persons in their office hours.

People came to the doctor, so they told me, for the most trivial things, largely to get certificates that exempted them from going to work, so that they could get their disability pay; and, of course, if a man was only working half-time anyway, and the weather was bad, and he could get just about as much in staying home as going to the factory, he would obviously stay home. That took up much of their time, and they did not have time to see people who were really sick.

Senator Donnell: Doctor, do you have any illustration in mind as to the degradation of physicians that has occurred in other countries, or the decrease in their professional attainments or competitive desire or skill?

Dr. Goin: Not so long ago every young man who finished medicine in America and was reasonably ambitious tried his best to go to Germany and Austria for study. Now, everybody would give his right arm to come here. That is what has happened to their medical system. It is not as the direct result of this sort of thing, but it is coincidental.

The British doctors, I am told by British physicians, are almost reduced to a lower grade civil servant. The doctor does not have much freedom about what he does; his time is largely taken up with writing out statistical reports and certificates to purchase corsets and false teeth, and eye glasses and wigs, and that sort of thing, and the ones that I talked to were thoroughly disheartened.

Senator Donnell: You predict here in your statement that the enactment of this legislation will decrease the number of physicians produced annually, and that it will lower the quality of the young men who enter medicine. Do you want to amplify that point?

Dr. Goin: Of course, all we can do is to observe what has happened elsewhere. It is reasonable to assume that something like that will have to happen if you enact a law something like this. The average doctor in Great Britain now has an annual income of about $5,000. Out of that he has to maintain his office and pay assistants, and if he is fortunate enough to have an automobile he has to maintain that.

I do not see why a young man would subject himself to the severe discipline of at least two years in college, at least four years in medical school, at least one year in hospital training, for the purpose of earning the amount of money that he could have earned the first six months after he had started his college course.

Senator Donnell: Have you ever seen the book or books of regulations and laws under the British law?

Dr. Goin: Yes.

Senator Donnell: Tell us about how large these books are.

Dr. Goin: Well, the official book of regulations contains 1310 pages. Then they had a second book which was known familiarly as the doctor's Bible, and that was a digest of these regulations and between 500 and 600 pages. This book the doctor had to refer to constantly to see what he might or might not do.

Senator Donnell: Have you studied anything about New Zealand, with this type of thing?

Dr. Goin: I am moderately familiar with it.

Senator Donnell: Would you characterize your understanding of their experience?

Dr. Goin: I understand it has been a great failure, and it is a great national scandal. I know it has taken a great deal more money than they have ever been able to collect from it. It seems to me that 7 per cent of the national income has been taken to run that plan.

Senator Donnell: I intended to ask whether you had studied S. 1581, the Taft bill, and what your impression was about the bill.

Dr. Goin: With some small amendments, I would be prepared to support it. I have not studied it carefully but my general impression is favorable.

Senator Pepper: Do you know of any country which has adopted what we call national health insurance, compulsory prepayment for health care, which, once having established it, has repealed it?

Dr. Goin: I do not. I do not think that the people always know what they should have. I think they frequently have to be guided by people with more expert knowledge. What the people want I think they should and do get. That is the kind of country we have.

Senator Pepper: You would want to preserve the right of the patient who might have been abused and neglected to complain to somebody, would you not?

Dr. Goin: Of course.

Senator Pepper: Let us take the voluntary insurance plans that are now in effect. Let us take yours, the one initiated and operated by the physicians in California. How long does a member pay for whenever he joins up, for a day or a month or a year or what?

Dr. Goin: Well, a member who has a payroll deduction pays for the period of his pay check.

Senator Pepper: You use the payroll deduction method also? How long does a person pay for when he joins up?

Dr. Goin: When he joins an employed group he just joins for the period that his pay check covers. Usually it is two weeks or a month.

Senator Pepper: Supposing this individual feels that he wants to go around to see his doctor, and he is not there. He calls for the doctor, and the doctor does not come or he thinks that the doctor did not give him the care that he should have had. What does he do?

Dr. Goin: Just calls another doctor.

Senator Pepper: You mean that he calls another doctor who is part of the same program.

Dr. Goin: Everybody is part of it.

Senator Pepper: Every doctor in California is a member?

Dr. Goin: For practical purposes. We have 9,788, and I suppose there are 10,500 doctors practicing.

Senator Pepper: Suppose he complains; that he goes to the second doctor, and this doctor treats him and he does not give him the right kind of treatment. Then what does he do?

Dr. Goin: Go to a third doctor.

# Washington Letter

*(From a Special Correspondent)*

July 5, 1949.

### List of Final Witnesses Heard by Murray Subcommittee

Among those who were heard in the closing week of the Senate health subcommittee's hearings were: Dr. Joseph S. Wall, American Academy of Pediatrics, who registered objection to compulsory health insurance; R. D. Murphy and Edward H. O'Connor, representing insurance interests, who likewise expressed opposition to the Thomas-Murray-Dingell bill, the latter also criticizing the Hill and Taft bills because they would exclude commercial medical and hospital care plans from participation in benefits, being limited to nonprofit programs; Dr. William J. Stickel and Dr. Albert Bailey, recommending, respectively, that chiropodists and osteopaths be included among the health service practitioners eligible to participate in the various types of programs under consideration; Dr. Leona Baumgartner, associate chief, and Katherine Lenroot, chief, the U. S. Children's Bureau, who endorsed expansion of federal efforts in the maternal and child health field, and Robert A. Hornby, San Francisco businessman and representative of the U. S. Chamber of Commerce, who detailed the reasons for the chamber's opposition to compulsory health insurance. Arguments to the contrary were presented by Mrs. Lula Evanson and Angus McDonald, in behalf of the National Farmers Union. Lloyd C. Halvorson, economist for the National Grange, said that his organization is dubious of compulsion and emphasized the need of making progress in such noncontroversial fields as aid to local public health agencies and expansion of medical research.

Co-sponsors of the so-called Flanders-Herter bill who urged its adoption in testimony before the Murray subcommittee were senators Flanders and Ives and representatives Javits, Case and Herter. This plan, they said, would obviate compulsory health insurance and make adequate medical and hospital coverage available—at moderate cost—to the lowest-salaried workers on a voluntary basis.

### Hospital Expansion Favored Before House Group

On June 29 and 30, numerous members of the House and spokesmen for hospital and farm groups appeared before or filed statements with the Priest subcommittee for the purpose of endorsing proposed liberalization of the Hill-Burton Act to accelerate construction of hospitals throughout the country. Witnesses included George Bugbee, executive director of American Hospital Association, who urged that the federal contribution (now 33⅓ per cent) be made no higher than 40 per cent; Rev. Dr. John G. Martin, of American Protestant Hospital Association, who stressed the progress being made by Blue Cross plans; Hugh H. Murray Jr., of Raleigh, N. C., representing the National Association of Mutual Insurance Agents, who asked that controversial subjects such as health insurance be laid aside while action is being taken to increase medical manpower, and House members from nearly one third of the states.

When the House health subcommittee resumes its hearings, on July 6, it will be to take up pending proposals for increased federal funds for local public health units and for research in child health.

### Dr. Hugh G. Grady Heads American Registry of Pathology

Appointment of Dr. Hugh G. Grady as scientific director of the American Registry of Pathology has been announced by Brig. Gen. Raymond O. Dart, director of the Army Institute of Pathology. Approved by Surgeon General Raymond W. Bliss, the appointment was recommended by the Committee on Pathology, National Research Council. Dr. Grady succeeds Col. James E. Ash, U. S. Army Medical Corps (Ret.), who is retiring from active participation in registries. A native Philadelphian, Dr. Grady received his M.D. from Jefferson Medical College in 1934 and during the late war served as pathologist and executive officer of the Army Institute of Pathology.

# Medical Legislation

## STATE LEGISLATION

### Illinois

**Bill Introduced.**—S. 636 proposes to direct the board of trustees of the University of Illinois to prescribe minimum qualifications for **admission to the College of Medicine** of the University. The proposal would also require that each class of first year students admitted to the College of Medicine shall include at least three residents of each senatorial district in the state, provided that there are three or more applicants from such district who possess the minimum qualifications.

### Michigan

**Bills Enacted.**—H. 446 has become Public Act No. 226 of the Acts of 1949. It provides that any program of **instruction in sex hygiene** in the public schools shall be supervised by a registered physician, a registered nurse or a person holding a teacher's certificate, qualifying such person as supervisor in this field. No instruction in birth control shall be included in such courses. S. 91 has become Public Act No. 164 of the Acts of 1949. It provides that, in order to afford adequate protection to all children of the state against certain dangerous diseases, every physician engaged in general practice and every county, district, city, village and township health department employing a full time health officer shall **offer immunization treatments** for protection against diphtheria, whooping cough, tetanus and smallpox to all children over 6 months of age at their first visit to the doctor's office or health department except when it is contraindicated; provided that in no instance shall a health officer or any member of his staff give such immunization treatments to any child without the written consent of one of the parents or the guardian or to any child whose parents or guardian have religious objections to such treatments. The law also requires health departments to offer free immunization treatments to the public at large for protection against smallpox and typhoid in the event of an epidemic or threatened epidemic of such diseases. S. 121 has become Public Act No. 278 of the Acts of 1949. It requires the state health commissioner within the limits of financial ability to establish and administer a program or service of assisting local health departments, schools or other community groups in developing and maintaining **periodic hearing screening tests** among children for the purpose of seeking out children who may have hearing impairment so they may secure proper and necessary care and attention.

### Missouri

**Bills Introduced.**—H. 164 proposes to make it unlawful for any employer to require any employee or applicant to pay the **cost of a medical examination** or the cost of furnishing any medical records required as a condition of employment. H. 264 proposes the enactment of a new law regulating the licensing of **registered nurses**, licensed practical nurses and registered obstetrical nurses. H. 2073 proposes the creation of a state **board of medical examiners** to take over the duty of licensing and regulating practitioners of medicine, surgery and midwifery now regulated by the state board of health. S. 237 proposes to authorize all counties of the first class to appoint a **pathologist** to have all of the rights and duties and powers of a deputy coroner.

### New Hampshire

**Bills Enacted.**—H. Con. Res. 13 was approved May 26, 1949. It memorializes the Congress of the United States to enact S. 102, entitled an act to amend the Public Health Service Act to provide for research and investigation with respect to the cause, prevention and treatment of **multiple sclerosis and related neurologic diseases.** H. 245 has become chapter 241 of the Laws of 1949. It requires any physician or hospital superintendent to immediately report to the local board of health any person under his care or observation who is affected with a **communicable disease** or any other condition requiring reporting by the physician.

### South Carolina

**Bills Enacted.**—H. 1387 has become Governor's Act No. 610 of the Acts of 1949. It amends the act relating to the **practice of naturopathy** by setting forth grounds for the revocation of a license, by requiring a two year premedical course, rather than one, and by making licensure discretionary, rather than mandatory, on the part of the board. H. 1568 has become Governor's Act No. 580 of the Acts of 1949. It provides that a representative of the State Nurses Association, the State Dental Association and the State Pharmaceutical Association shall be appointed to membership of the Executive Committee of the **State Board of Health.**

# Coming Medical Meetings

International Congress of Biochemistry, Cambridge, England, Aug. 19-25. Lt. Col. Francis J. Griffin, 56 Victoria St., London, W.C.1, Organizer.

Montana State Medical Association, Butte, Aug. 1-4. Dr. Herbert T. Caraway, 115 N. 28th St., Billings, Secretary.

West Virginia State Medical Association, White Sulphur Springs, The Greenbrier, Aug. 4-6. Mr. Charles Lively, 1031 Quarrier St., Charleston. Executive Secretary.

# GOVERNMENT SERVICES

## ARMY

### MEDICAL SUMMER CAMPS

The first contingent of college students who will attend R.O.T.C. summer encampments at Brooke Army Medical Center, Fort Sam Houston, Texas, is under way for six weeks of training. The students have been divided into two groups. Training for the basic group, those men with no previous military experience, who have completed only their freshman year in medical school, or those who prefer field training, is conducted by the *Medical Field Service School at the Medical Center.* For medical students who previously served with the armed forces, a hospital camp has been set up and, under the direction of Brooke General Hospital, offers a clinical clerkship course. In addition to military studies, the students attend regular hospital and staff conferences and observe diagnostic and treatment procedures throughout Brooke General Hospital.

Of the students now attending the Brooke General Hospital Camp, 80 have finished their second year of medical study and 43 have completed the third year. A large number of them hold reserve commissions as line officers, but have preferred through the R.O.T.C. method to obtain reserve commissions in the Medical Corps. Available clerkships for the summer encampment are 40 in general medicine; 15 in general surgery; 8 in orthopedics; 15 in laboratory sciences; 8 in diseases of eye, ear, nose and throat; 6 in obstetrics and gynecology; 6 in urology; 6 in anesthesiology; 30 in neuropsychiatry, and 1 in radiology. Men who have completed only the first two years of medical school are invited to clerkships in general medicine, general surgery, neuropsychiatry and laboratory sciences. Every effort is made to assign the students to the specialty of their preference, and, once they are assigned, there is no rotation of services during the six week training period.

Because of the large membership in medical R.O.T.C. units, the same six week course for both basic and advanced students will be presented to a second group in August.

### ACCEPTED FOR ADVANCED TRAINING

The following medical officers have been accepted for advanced training in the civilian institutions indicated:

Lt. Colonel David H. Naimark, University of Buffalo, Buffalo, Internal Medicine.

Lt. Colonel Larry A. Smith, Jefferson Medical College of Philadelphia, Philadelphia, Internal Medicine.

Lt. Colonel John S. Oartel, University of Pennsylvania, Philadelphia, Oral Medicine.

Major Richard J. Brightwell, University of Colorado, Denver, Internal Medicine.

Captain John M. Geary, University of North Carolina, Raleigh, N. C., Entomology.

Captain Warren H. Kimsey, Neurological Institute, New York, Neurological Surgery.

First Lt. John H. Angell, Johns Hopkins Hospital, Baltimore, Gynecology.

First Lt. George H. Flessas, St. Mary's Hospital, Madison, Wis., Intern Training.

First Lt. Rudolph M. Jarvi, Harper Hospital and Children's Hospital, Detroit, Pediatrics.

First Lt. William F. Hughes Jr., Saint Luke's Hospital, Cleveland, Medicine.

*First Lt. Arthur W. Adams, Ellis Hospital, Schenectady, N. Y.,* Surgery.

First Lt. Robert F. Hufner, University of Colorado Medical Center, Denver, Pathology.

First Lt. Arnold J. Capute, Flower and Fifth Avenue Hospitals, New York, Pediatrics.

First Lt. Robert H. Wildhack, Millard Fillmore Hospital, Buffalo, Obstetrics & Gynecology.

First Lt. Gilbert A. Varnell, Bridgeport Hospital, Bridgeport, Conn., Obstetrics.

### SURGEON GENERAL PLACED DIRECTLY UNDER CHIEF OF STAFF

The Department of the Army has announced that the Surgeon General will be placed directly under the Chief of Staff to facilitate his direct access to the Secretary of the Army and to the Chief of Staff. General Omar N. Bradley, Chief of Staff, said that this same organizational pattern is being implemented throughout the Army so that all medical officers will have direct access to their respective commanders.

## PUBLIC HEALTH SERVICE

### LOWEST DIPHTHERIA INCIDENCE ON RECORD

The National Office of Vital Statistics' report on communicable diseases for the first sixteen weeks of 1949 indicates that the incidence of diphtheria is probably lower for the country as a whole than for any corresponding period on record. Typhoid and meningococcic meningitis also had lower morbidity levels. The report was based on weekly telegraphic reports sent the National Office of Vital Statistics by state health departments.

### 259 INTERNSHIPS

Beginning July 1, 1950, the Veterans Administration will offer 259 internships to qualified graduates of recognized medical schools in thirteen of its hospitals. The intern program will be conducted under the direction of the Deans' Committees in cooperation with certain medical schools close to the hospital. This program follows by four years VA's establishment of residencies for teaching purposes and is the next step in expanding the teaching facilities in hospitals in line with policy originally set up with the establishment of the Deans' Committee. There will be three types of internships—straight internal medicine, straight general surgery and rotating. Internships will be set up in the following VA Hospitals: Los Angeles; Van Nuys, Calif.; Newington, Conn.; Chamblee, Ga.; Dearborn, Mich.; Oklahoma City, Okla.; Memphis, Tenn. (Kennedy); Nashville, Tenn.; Dallas, Texas; Houston, Texas; McKinney, Texas; Salt Lake City, and Richmond, Va. (McGuire). Application blanks may be secured after August 1 by writing to the representative of the local Deans Committee for each hospital.

### WORLD HEALTH ORGANIZATION FELLOWSHIPS

Two specialists in tropical diseases from India and two from China, carrying on advanced studies on fellowships granted by the World Health Organization, are now guest researchers at the National Institutes of Health, research branch of the Public Health Service. Dr. Amar Ray and Dr. Simili Ramakrishnan are assistant directors of the Malaria Institute of India, and both served as lieutenant colonels in the Indian Army during the war, organizing and directing malaria research and control activities. Dr. Ray will concentrate on malaria chemotherapy and chemoprophylaxis, while Dr. Ramakrishnan will investigate the host-parasite relationship in man and birds.

Dr. Tzu-Ta Chen and Dr. Pei Kai Kuo of China will spend a few weeks in the Laboratory of Tropical Diseases, observing research methods in parasitology. Dr. Chen is on leave of absence from the Nanking Central Hospital, and Dr. Kuo was most recently connected with the National Defense College at Shanghai.

### CLINICS ON CAUDAL ANALGESIA IN CHILDBIRTH

The Surgeon General announces that a series of clinics at leading European universities will be initiated by Dr. Robert A. Hingson on the technic for continuous caudal analgesia for the control of childbirth. The clinics are scheduled at Oxford, Cambridge, Leeds, Newcastle, Edinburgh, Geneva, Paris and Stockholm. Dr. Hingson, who with Dr. Waldo B. Edwards, another Public Health Service officer, developed this technic in the Staten Island Marine Hospital, also lectured on this subject before the British Medical Association at its annual meeting in Harrogate late in June. Physicians from 32 foreign countries already have come to the United States to study this subject. Dr. Hingson, who was commissioned in the Public Health Service in 1939, for the past year has been on a teaching and research assignment at Johns Hopkins University School of Medicine, Baltimore.

### MOVIE ON BREAST CANCER

The National Cancer Institute of the U. S. Public Health Service has granted $60,000 to the American Cancer Society to aid in the production of a movie to show women the basic facts about breast cancer, including a simple technic for periodic self inspection of the breasts. The American Cancer Society will match the grant for this film, and these funds will also finance the completion of four additional films for physicians dealing with cancer of the lung, uterus, mouth and gastro-intestinal tract. Dr. Austin V. Deibert, Chief of the National Cancer Institute Control Branch, said that the mortality rate for breast cancer, about 17,000 deaths annually, could be cut in half if women were alert to the early signs and symptoms and sought prompt medical attention for breast tumors. Announcement of the grant followed a recommendation by the National Advisory Cancer Council and approval by Surgeon General Scheele.

### MEETING OF WATER POLLUTION CONTROL BOARD

The newly appointed Water Pollution Control Advisory Board held its first meeting in Washington May 9-10, to assist in the development of a master plan for safeguarding the quality of the nation's water resources, the Surgeon General of the Public Health Service announced. The board, appointed in part by the President and in part by government department heads, reviewed policies and programs of the Public Health Service and will assist in drawing up a blueprint for the remainder of the five year program called for by the Act. One immediate problem will be the development of comprehensive programs for controlling pollution of interstate waters and tributaries. It is contemplated that the board will meet from time to time to review subsequent developments.

The Water Pollution Control Act aims to help states control pollution of the nation's streams and lakes. A comprehensive water pollution control program to be carried out jointly with the Federal Works Agency is being set up by the Public Health Service. This program is to be carried out under a broad policy laid down by Congress to recognize, preserve and protect the primary responsibilities and rights of states in controlling water pollution.

### TRAINEES FROM FOREIGN COUNTRIES

The Public Health Service reports that on Jan. 1, 1949, there were 82 trainees from 24 countries who were in the United States attending schools or working under programs administered by the Educational Programs Branch. With this training program now in its third year, 62 of the 82 trainees were physicians, 8 were public health workers and 12 were nurse trainees. Seventeen of the physicians were from the Philippine Islands, 6 from Germany, 5 from China, 4 each from Turkey and India, 2 from Syria, 1 each from Africa and Iraq and 22, the largest number, from Latin America. The physicians were receiving training in numerous fields, among others, surgery, internal medicine, maternal and child health, infectious diseases, cancer control, malariology and pharmacology.

### PERSONAL

Dr. James A. Doull, chief of the Office of International Health Relations of the Public Health Service, has been detailed to the American Leprosy Foundation (Leonard Wood Memorial) as director of research with headquarters in Washington. Studies will be made on the epidemiology of leprosy and methods of treatment. Dr. Doull was chairman of the Medical Advisory Board of the foundation from 1940 to 1943.

## MISCELLANEOUS

### POSITIONS OPEN AT ST. ELIZABETH'S HOSPITAL

The U. S. Civil Service Commission announces a medical officer examination for filling rotating intern psychiatric resident and surgical resident positions in St. Elizabeth's Hospital, Washington, D. C. The salaries for rotating interns are $2,200 for the first year and $2,400 for the second year; the salaries for psychiatric resident range from $2,400 to $4,100 a year, and for surgical resident, from $3,400 to $4,150.

Applicants for the rotating intern positions must be third or fourth year students in an approved medical school. Applicants for psychiatric resident and surgical resident positions must be graduates of a medical school with the degree of doctor of medicine, and must have completed a full year in an approved rotating internship. In addition to those requirements, applicants for appointment as surgical resident must have completed three full years as residents-in-training in surgery in an approved residency. No written test is required. The maximum age limit of 35 years is waived for persons entitled to veteran preference. Information and application forms may be obtained at most first and second class postoffices, from civil service regional offices or from the U. S. Civil Service Commission, Washington 25, D. C.

### POSITIONS OPEN IN THE CANAL ZONE

Permanent Civil Service appointments for physicians are available in the Panama Canal Medical Service, starting salaries $5,599 and $6,540 a year, free transportation to the Canal Zone provided and two months' paid vacation (including time lost by illness). The Panama Canal Health Department operates several hospitals and well equipped dispensaries and keeps constant vigilance over health conditions in the Canal Zone and Colon and Panama City. Since the number of appointments is limited, early application is suggested.

Requirements for medical positions starting at $5,599 are: graduation from an approved medical school, license to practice in a state, ability to pass a physical examination and one year's internship in a hospital approved by the American Medical Association; requirements for medical positions starting at $6,540 are the same except that a minimum of three years of postinternship experience is required. Living conditions are comparable to those in a small town in the United States except for the tropical climate. The public school system compares favorably with modern American school systems, and excellent facilities are provided for children of employees without charge from kindergarten through high school. There are churches and good highways, as well as libraries, movies, golf courses, hunting and fishing. Physicians interested should address their applications to the Chief of Office, The Panama Canal, Washington 25, D. C.

### ALLERGENS RESEARCH DIVISION

On May 15 the Honor Awards Ceremony of the Department of Agriculture was held and the Allergens Research Division of the Bureau of Agriculture and Industrial Chemistry received the following citation: "For outstanding achievement in fundamental chemical and biological research on the allergenic components of agricultural products, which has markedly advanced scientific knowledge of allergens, made possible more accurate methods for the quantitative determination of allergenic activity, and contributed significantly to wider utilization of farm commodities and to the general health and welfare."

The staff members of this unit are: Henry Stevens, Ph.D., head; Joseph R. Spies, Ph.D., and E. J. Coulson, Ph.D., biochemists; Dorris C. Chambers, M.S., chemist, and Harry S. Bernton, M.D., clinical specialist in allergy and allergist to Providence Hospital, Washington, D. C.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## ARKANSAS

**State Medical Election.**—At the annual meeting in April the following officers of the Arkansas Medical Society were elected: Drs. Euclid M. Smith, Hot Springs, president; Earle H. Hunt, Clarksville, president-elect; Paul L. Mahoney, Little Rock, treasurer, and William R. Brooksher, Fort Smith, secretary.

## CALIFORNIA

**Personals.**—Dr. Lawrence Kolb, medical director, has been appointed acting director of the state's mental hygiene department.——Dr. William C. Voorsanger, San Francisco, has received the annual award of the California Tuberculosis and Health Association for meritorious service in tuberculosis control.

**Psychiatric Fellowship.**—A twelve month fellowship has been established in the psychiatric department of the Cedars of Lebanon Hospital in Los Angeles. The fellowship carries no stipend, but room and board will be provided. Interested physicians should apply to Dr. Eugene Zisking, Director, Psychiatric Clinic, Cedars of Lebanon Hospital, 1306 N. Berendo St., Los Angeles 27.

**Mount Zion Hospital Reunion.**—Mount Zion Hospital in San Francisco Alumnae Association is planning a reunion the early part of 1950, when its new 300 bed hospital will be completed. The hospital directorate and the alumnae association would like to hear from all doctors who have served on the staff of the hospital. Replies should be addressed to Donna Osborn, R.N., 255 9th Ave., San Francisco, Evelyn Rhein, R.N., 419 Gonzalez Drive, San Francisco, or Elsie Nathan, R.N., 839 Post St., San Francisco.

**Part-Pay Referrals Reactivated.**—The Alameda County Medical Association has reactivated its "part-pay referral plan" as implementation of its published guarantee of medical care to all. The plan was first put into effect in the county in 1932, but has been dormant since 1942. A medical social service consultant has been added to the society's staff for closer coordination of the agencies whence come the majority of the part-pay referrals. The screen is set up by the social service department of the county institutions and the medical social service consultant of the association. The social worker makes no attempt to state fees; details of arrangements for payment remain with the physician.

## COLORADO

**Dr. Darley Named Vice President of University.**—Dr. Ward Darley, dean of the school of medicine, has been appointed a vice president of the University of Colorado and dean of the department of medicine, which includes the school of medicine, the school of nursing, and their teaching hospitals, Colorado General and Colorado Psychopathic. Dr. Darley's new appointment completes an administrative reorganization begun last October, when he was placed in charge of all health science services at the university's Denver Medical Center. Robert C. Lewis, Ph.D., was recently appointed dean of the school of medicine.

**Chest Roentgenographic Survey.**—The mass chest roentgenographic survey begun June 21 will extend until August 31 to include the population of the city of Denver and the three adjoining counties, Adams, Arapahoe and Jefferson. The goal is to examine 350,000 persons over 15 years of age. The project is sponsored by official and voluntary agencies and the medical societies of the four counties and will be conducted with the assistance of the U. S. Public Health Service. Facilities will be provided for a definitive diagnosis in cases with abnormal findings. The special temporary Diagnostic Center will be staffed by physicians from the community with experience in chest diseases. Patients will then be referred to their private physicians or clinic for fellow-up care.

## ILLINOIS

**Birth Rate Drops.**—There were over 11,000 fewer babies born in Illinois during 1948 than in the peak year of 1947. This and the growth of population brought the birth rate down from 22.9 to 20.9 per 1,000 population. This is considered a sharper drop than for the United States as a whole, where the 1948 rate was 24.4 and 25.8 in 1947. The natural increase in population during 1948 (births minus deaths) was 91,000 persons. The state had an appreciably lower mortality rate for almost every cause of death during 1948, and the actual number of deaths was lower despite the larger population, 10.4 for 1,000 population, the state's lowest record.

### Chicago

**Institute of Nuclear Studies.**—Across the street from the football stand where he built the first atomic pile, Enrico Fermi, distinguished service professor of physics at the University of Chicago, on June 21 laid the cornerstone for the $7,500,000 laboratory for nuclear, biologic and metallurgic research. Robert E. Wilson, chairman of the board of Standard Oil of Indiana and a trustee of the university, and Kenneth S. Pitzer, director of the Atomic Energy Commission's research division, were the principal speakers at a luncheon following the cornerstone ceremony. The four story structure, covering half a city block at 57th Street between Ellis and Drexel avenues, is designed with three wings to provide office and laboratory space for each of the four institutes of the research center. A basement and one story laboratory houses the new syncrocyclotron, which is scheduled for operation early in 1950. One of the three largest cyclotrons in the world, this $2,200,000 instrument was financed by the Office of Naval Research and public contributions to the university's Cancer Research Foundation. A 100,000,000 volt betatron for research on high energy gamma rays is located in the Accelerator Building. Many of the key men who operated the first pile are doing fundamental research in the institutes. Since 1947 twenty corporations, as industrial members of the institutes, have pledged $4,000,000 to support the program over a fifteen year period. The south corner wing of the building will be assigned to the Institute of Radiobiology and Biophysics for study of problems ranging from the nature of viruses to the fundamental processes of plant, animal and human growth. Laboratories are being built for the experimental study of micro-organisms. The Institute for Nuclear Studies, joining the Accelerator Building, will feature a two story lead-shielded laboratory for high voltage experimental research. A library, shops, drafting rooms and an optical laboratory are among the 300 rooms being set up in the institute building.

## LOUISIANA

**Geiger Medal Awarded.**—The 1949 winner of the Geiger Medal of Public Health at Tulane University, New Orleans, is Dr. Keene A. Watson, for his thesis and work concerning the Prevention of Homologous Serum Jaundice. The award, a gold medal, was presented to the university in 1929 by Dr. and Mrs. Jacob C. Geiger to be awarded to a senior or graduate student for a thesis on some public health problem of the Southern states or countries contiguous to the Southern states. Dr. Geiger, an alumnus of Tulane, is now the director of public health of the city and county of San Francisco.

**Mental Hospital Annex.**—A five story annex to De Paul Sanitarium, New Orleans, is expected to be completed by the end of 1950. The new building, which will be named Rosary Clinic, will add 100 beds to the hospital. The fifteen special therapeutic recovery rooms for the acutely ill will be sound proofed and air conditioned. Intercommunication systems will also be installed and radio facilities. The fifth floor is to be a recreation area, with special rooms, a corrective gymnasium and two roof gardens for sun baths. De Paul Sanitarium is administered by the Daughters of Charity of St. Vincent de Paul.

## MINNESOTA

**State Medical Election.**—The Minnesota State Medical Association at its meeting in St. Paul, May 9-11, chose Dr. Frank J. Elias, Duluth, as president-elect. Drs. Benjamin B. Souster, St. Paul, and William H. Condit, Minneapolis, were reelected secretary and treasurer, respectively. Drs. George A. Earl, St. Paul, and Archibald E. Cardle, Minneapolis, were elected American Medical Association delegates, with Drs. William W. Will, Bertha, and Ernest M. Hammes, St. Paul, as alternates.

**Personals.**—Dr. Ernst Gellhorn, Minneapolis, professor of neurophysiology at the University of Minnesota, has been invited to address the Royal Society of Medicine in London on September 13 on "The Physiologic Basis of Shock Therapy of Mental Diseases."——The Surgeon's General Office has awarded a Fellowship of the Mental Institute of Hygiene for research in neurology at the University of Minnesota to Captain John. W. Schut, Maple Lake, Minn., who will be discharged from the Army July 25.

## MISSOURI

**Dr. Sacks Goes to Yale.**—Dr. Ernest Sacks, formerly emeritus professor of neurologic surgery at Washington University School of Medicine, St. Louis, resigned June 1. He has accepted an appointment as research associate in physiology at Yale University Medical School, New Haven, Conn. Dr. Sacks, a graduate of Johns Hopkins University School of Medicine, Baltimore, 1904, was clinical professor of neurosurgery at Washington University 1919-1936, when he was made emeritus professor of neurologic surgery.

## NEW MEXICO

**State Medical Election.** — The New Mexico Medical Society at its annual meeting early in May installed Dr. James W. Hannett, Albuquerque, as president and chose Dr. Ira J. Marshall, Roswell, president-elect, and Dr. Harold L. January, Albuquerque, secretary treasurer.

## NEW YORK

**Hutchings Memorial Award.**—A memorial award of $100 for an outstanding contribution to psychiatry from a public mental institution has been announced by the Richard H. Hutchings Memorial Committee. The award, in memory of Dr. Hutchings, who spent his life in the state hospital field, is from an anonymous donor and is presented through Dr. C. Charles Burlingame of the Institute of Living, Hartford, Conn. The award is without restriction as to type of professional achievement. Scientific articles, reports or nominations for the award may be submitted to Dr. Harry A. Steckel, 130 Circle Rd., Syracuse 10, or to Dr. Newton Bigelow, director of the Marcy State Hospital, Marcy, and secretary-treasurer of the committee. Dr. Hutchings, who died in October 1947, was head of St. Lawrence State Hospital, Ogdensburg, and later of Utica State Hospital, and for many years taught psychiatry at Syracuse University College of Medicine.

### New York City

**Scholarships in Eye Conservation.**—Four New York University-Bellevue Medical Center physicians were awarded scholarships totaling $2,000 for research in fields related to eye conservation at a luncheon of the Lions Club of New York June 21. Mr. Walter Hoving, guest speaker at the luncheon, presented a check for the amount to the school through Dr. Daniel B. Kirby, professor of ophthalmology, New York University Post-Graduate Medical School. The check represents the fourth annual gift of the Lions Club in aid of the medical center's program of postgraduate research devoted to the alleviation and prevention of blindness.

**Personals.**—Dr. Mary M. Crawford, for many years head of the health department of the Federal Reserve Bank of New York, on June 22 received the Kappa Kappa Gamma Alumnae Achievement Award, in recognition of her contribution to the community.——Dr. Walter T. Dannreuther, professor of obstetrics and gynecology at New York Post-Graduate Medical School and Hospital, was presented the Alumni Medallion for distinguished service to American Medicine at the annual commencement program of the Long Island College of Medicine last month. Dr. Dannreuther was a graduate in the class of 1906. ——Dr. Tibor de Cholnoky lectured at the Curie Institute in Paris on June 22 on "Surgical Treatment of Malignant Tumors of the Face." Dr. Cholnoky will return after Labor Day.

**Lectures in Biochemistry.**—Four Nobel prize winners and other leaders in the field of biochemistry and related sciences are scheduled to lecture at the New School for Social Research next fall. The lectures are part of an expanded program, which includes six courses on biochemistry offered as a public service without fee and given jointly by the New School and the Institute for Muscle Reseach under the direction of Dr. Albert Szent Gyorgyi. The other Nobel prize winners who will lecture are Dr. Otto H. Warburg of the Institute for Muscle Research, Dr. Otto Loewi, now research professor of pharmacology, New York University College of Medicine, and Dr. Otto Meyerhof, research professor in physiology, University of Pennsylvania, Philadelphia. The courses, of seven to sixteen weeks each, are of two kinds. The first two, "Dynamics of Living Things" and "Dynamics of Muscle as a Living System," are addressed primarily to laymen, and it is in the first of these courses that the Nobel prize winners will appear. The remaining courses are designed especially for physicians and other scientists. These courses include "Biochemistry of Muscle," "Blood and Some Aspects of Its Functions," "Elementary Introduction to Quantum Mechanics and Some Biological Applications" and "Quantum Chemistry and Its Biological Applications." Drs. Andrew Paul, Ephraim Shorr and Harold G. Wolff join Drs. Kalman Laki and Stephen Rath and other members of the staff of the institute in giving the course, "Blood and Some Aspects of Its Functions."

## NORTH CAROLINA

**North Carolina Medical Foundation.**—More than 200 physicians and laymen met at the University of North Carolina, Chapel Hill, May 28 and set up the Medical Foundation of North Carolina, the chief purpose of which is to create an endowment "to promote, by financial assistance and otherwise, all types of education, service and research in the fields of preventive and curative medicine at the medical and dental schools of the University; and to render assistance to industry, business and agriculture and to agricultural and industrial workers, through various programs designed to improve rural and urban health." Mayor L. P. McLendon, Greensboro attorney, was elected president of the foundation.

**Annual Pediatric Seminar.**—The annual Southern Pediatric Seminar will be held at Saluda, July 18-30, with Dr. Samuel F. Ravenel, as dean. This comprises a graduate course in diagnosis, prevention and treatment of diseases of children, designed primarily for general practitioners. Lecturers, who serve without compensation, represent most universities in the South. The registration fee is $25. The program lists the following physicians as special lecturers: Joseph R. Bowman, Johnson City, Tenn.; James G. Hughes, Memphis, Tenn.; Weston M. Kelsey, Winston-Salem, N. C.; J. Howard Stokes, Florence, S. C.; William A. Reilly, Little Rock, Ark.; C. Nash Herndon, Winston-Salem, N. C., and John W. R. Norton, Raleigh, N. C., and Frank Lammons, D.D.S., Atlanta, Ga.

## OKLAHOMA

**Medical Research Foundation.**—Construction has started on the main building of the Oklahoma Medical Research Foundation, which is to be located adjacent to the Oklahoma School of Medicine in Oklahoma City. The three story building is to be completed in June 1950. Fund raising was begun in 1947, and over $2,000,000 of the $3,000,000 goal has been pledged. The site was donated in 1947. The idea of the research foundation began with a small group of the alumni of the Oklahoma School of Medicine in 1944. Sir Alexander Fleming was the principal speaker at cornerstone-laying exercises and participated in the AMA-NBC radio broadcast of dedication ceremonies July 2.

## WEST VIRGINIA

**New State Board of Health.**—Governor Patteson has announced the appointment of members of the new State Board of Health, created by the legislature this year. The bill was sponsored in the legislature by the state medical association. Dr. Paul E. Prillaman, Ronceverte, was appointed a member for a nine year term. Eight other members were appointed for terms as follows: J. Stanley Turk, Wheeling, hospital representative, eight years; Dr. Russel B. Bailey, Wheeling surgeon, seven years; E. O. Wiseman, Fayetteville pharmacist, six years; Mrs. Katherine M. Fisher, Moorefield, citizen representative, five years; Roy W. Eshenaur, osteopathic physician, Point Pleasant, four years; William M. Jarrett, Charleston dentist, three years; J. D. Evans, Logan, citizen representative, two years, and Dr. Peyton R. Higginbotham, Bluefield physician, one year. Dr. Newman H. Dyer is the present state health commissioner. On July 1 his title was changed to state director of health; he will serve as the executive officer of the State Board of Health.

**State to Register All Physicians.**—The registration of all doctors in West Virginia was undertaken by the state health department when the new biennial registration law became effective July 1. The registration fee is $2 for a two-year period. The program will be supervised by the new eleven-member Medical Licensing Board. The biennial registration is provided for under the provisions of H.B. 134, passed by the legislature at the regular session in 1949. The bill was sponsored by the West Virginia State Medical Association and was passed without opposition in the legislature.

Licenses of physicians who fail to comply with the new act will be automatically canceled by the board, and continued practice after cancellation will be construed as practicing without a license. Doctors who fail to receive the blank application for registration by July 6 are requested to bring the matter to the attention of the state health department so that duplicate forms may be mailed. Communications concerning registration should be addressed to Dr. N. H. Dyer, State Health Department, Charleston 5, W. Va.

## GENERAL

**University of Innsbruck.**—All graduates or former associates of the University of Innsbruck, Austria, are requested to send their addresses to the "Rektorat der Universitaet Innsbruck (Doktoren-Kollegium), 52 Innrain, Innsbruck, Tyrol, Austria," in order that they may be sent university bulletins.

**Nurses and Poliomyelitis.**—An appropriation of $10,000 from the National Foundation for Infantile Paralysis will assist the American Nurses Association to establish an inventory of registered nurses. During poliomyelitis epidemics it is essential to recruit large numbers of nurses. The usefulness of such an inventory will not, however, be limited to poliomyelitis. Data will be obtained concerning education and special preparation and experience in all nursing fields.

Continuance of advisory service to public health agencies and hospitals in nursing care of the infantile paralysis patient and planning for possible poliomyelitis epidemics was assured with the announcement June 29 of a March of Dimes grant of $64,718 to the National Organization for Public Health Nursing. Thirteen cities and towns in North Carolina and five in California were visited during last year's poliomyelitis outbreak as part of this service. This year conferences on nursing care have been held at San Francisco, Cincinnati and Kenosha, Wis.

**Foundation Allocates March of Dimes Funds.** — The National Foundation for Infantile Paralysis announced June 30 that almost $2,000,000 additional March of Dimes funds to step up research and professional education in the field of poliomyelitis have been allocated to various research laboratories and institutions throughout the nation. The midyear grants and appropriations bring to more than $2,500,000 allocated by the foundation for research and education projects this year, and the total since establishment of the organization in 1938 to more than $25,600,000. Thirteen medical schools and institutions from coast to coast share the new grants for virus research.

An appropriation of $20,000, to be administered by National Foundation headquarters, will be used to determine the role of flies in the transmission of human poliomyelitis. The $96,566 for the study of after-care of infantile paralysis patients was allocated among eight medical schools and hospitals. Appropriations for professional training, totaling $680,000, included $225,000 for physical therapy scholarships, $100,000 for scholarships in medical social work, $100,000 for fellowships in physical medicine and $50,000 for fellowships in the training of physicians in public health.

**Exchange Fellowships in Cancer Research.**—The American Cancer Society in conjunction with the British Empire Cancer Campaign is offering a number of British American Exchange Fellowships in Cancer Research. These fellowships, awarded by the society on the recommendation of the Committee on Growth of the National Research Council, are offered to the citizens of the United States for advance training and experience in Great Britain, where opportunities exist for study in facets of research in malignant disease not widely available in this country. Similar fellowships are awarded by the British Empire Cancer Campaign to British scientists for study in the United States. Fellowships are open to citizens in the United States who possess a degree of Doctor of Medicine, Doctor of Philosophy or Doctor of Science. They are intended for young men and women embarking on a career in clinical medicine or basic research, and also for more mature candidates desiring to extend their fields of competence in these subjects. Applications should state the institution where the fellow plans to work in Great Britain, the person under whom the fellow desires to work, what problems he intends to investigate and when he wishes to start. The annual stipend will be £1,000 ($4,020). An allowance of $600 is made for travel to the site of the fellowship. University staff appointment with teaching duties agreeable to the fellow is permitted, provided it carries no additional salary and provided it is acceptable to the Committee on Growth, the American Cancer Society, and the British Empire Cancer Campaign. No other remunerative work will be permitted during the tenure of the fellowship.

**Psychological Research Council for the Blind.**—This group has been organized to encourage, initiate and coordinate on a voluntary basis research to help the blind in effecting personal, social and vocational adjustment. Michael J. Shortley, Washington, D. C., director of the Federal Security Agency's Office of Vocational Rehabilitation, announced the formation of the committee and stated that he is requesting that it serve in a consultative capacity. At the second meeting of the council in Washington, D. C., on May 16-17 Dr. Samuel P. Hayes, director of research at the Perkins Institution and the Massachusetts School for the Blind, Watertown, Mass., was elected chairman; Wilma Donahue, director of the Bureau of Psychological Services in the Institute for Human Adjustment, University of Michigan, Ann Arbor, was chosen vice chairman-elect. Salvatore G. DeMichael, psychologic consultant, Office of Vocational Rehabilitation, Washington, D. C., was elected secretary. Other members are: Mrs. Harry H. Bauman, Philadelphia; Gabriel Farrell, Watertown, Mass.; Berthold Lowenfeld, Berkeley, Calif.; Lorenz A. Meyer, Washington, D. C.; Mr. Stanley Potter, St. Paul; Mr. Harry E. Simmons, Tampa, Fla., and C. R. Strother, Seattle, Wash.

**Prevalence of Poliomyelitis.**—Reports of cases of poliomyelitis for the periods indicated have been received from the Division of Public Health Methods, U. S. Public Health Service:

## Marriages

Alexander Charles Mitchell, New York, to Miss Charlotte Christine Beckwith of Riverdale, N. Y., June 4.

Wendell Howard Tiller, Spartanburg, S. C., to Miss Martha Estelle Ivey of Albemarle, N. C., May 28.

Roy Alexander McCall to Miss Grace Runyan, both of Sevierville, Tenn., June 1.

Wilson David Rees, Girard, Ohio, to Miss Janet Ann Wilder of Lucasville, May 28.

# Deaths

**Ray Lyman Wilbur** ⊕ President of the American Medical Association in 1923-1924, died of heart failure at his home in Palo Alto, Calif., June 26, aged 74. Dr. Wilbur was born in Boonesboro, Iowa, April 13, 1875, and moved to California in his youth. He graduated from Riverside High School, and received an A.B. degree from Leland Stanford Junior University, San Francisco, in 1896 and while serving as instructor in physiology the following year received an A.M. degree. In 1899 he graduated from Cooper Medical College of San Francisco, which in 1908 became the medical department of Leland Stanford University but retained its title until 1912. He was lecturer and demonstrator in physiology at Cooper Medical College from 1899 to 1900, and assistant professor of physiology from 1900 to 1903, when he went to Europe to study at Frankfurt, Germany, and London.

He then practiced medicine in San Francisco and in 1909 again went abroad to study at the University of Munich. He was appointed professor of medicine in the medical school of Stanford University in 1909 and in 1911 became dean of the medical faculty. On the retirement of president John Casper Branner in 1915, the trustees of Stanford University, in recognition of his extraordinary administrative ability, selected Dr. Wilbur to be president of the university, in which position he served with great distinction until he became chancellor in 1943. With the entrance of the United States into World War I, he was appointed chief of the Conservation Division of the United States Food Administration and for this work earned the gratitude of the civilized world.

Dr. Wilbur in 1920 was appointed to the Council on Medical Education and Hospitals of the American Medical Association, and, after the retirement of Dr. Arthur Dean Bevan, he served as chairman of the Council from 1929 until 1946. He had a prominent part in the expansion of the activities of the Council as a standardizing agency of medical schools, hospital internships and residencies and in the planning of graduate medical education. Dr. Wilbur further served the American Medical Association as Chairman of the Section on Pharmacology and Therapeutics in 1912 and 1913 and as delegate in 1914 and 1915. In the Association of American Medical Colleges he served as president in 1925 and for many years was on the executive council. From 1923 to 1940 he was trustee of the Rockefeller Foundation and a member from 1930 to 1940 of its general education board.

When Herbert Hoover became president of the United States, in 1929, he selected Dr. Wilbur to be Secretary of the Department of the Interior. From 1927 to 1935 he was chairman of the Committee on the Cost of Medical Care and author of its "First Three Years' Work." From 1929 to 1931 Dr. Wilbur served as chairman of the White House Conference on Child Health and Protection. He was honorary president and for many years president of the American Social Hygiene Association, which in 1943 awarded him the William F. Snow Medal. Honorary degrees were bestowed on Dr. Wilbur by the Universities of California, Arizona, Illinois, Pennsylvania, New Mexico, Pittsburgh, Chicago, Maryland, Duke, Princeton and Rochester, Puerto Rico, New York and Yale, the University of the State of New York, University of Southern California, Tusculum College and Wesleyan and Dartmouth colleges. Syracuse University in 1924 and Western Reserve University in 1931 conferred on him the degree of Doctor of Science. In 1920 he received the decoration of Commander, Order of Leopold II, and Chevalier French Legion of Honor, and in 1925 the Honor Cross of the German Red Cross. He was chairman of the Medical Council of the U. S. Veterans Bureau from 1924 to 1929 and in 1928 was the United States delegate to the sixth Pan American Conference in Havana. Dr. Wilbur served on the California State Board of Medical Examiners in 1902 and 1903, and in 1912 and 1913 was president of the American Academy of Medicine and in 1917 of the California Academy of Medicine. He was a fellow of the American Association for the Advancement of Science, a trustee of the Austin Riggs Foundation since 1944 and of the Nutrition Foundation since 1942; member of the medical advisory board of the American Leprosy Foundation since 1936; chairman of the Citizens Committee on Student Nurse Recruitment from 1944 to 1946, of the Baruch Committee on Physical Medicine since 1943 and of the advisory committee Army Specialized Training Program since 1943; consultant Navy College Training Program since 1943; member of the Youth Advisory Committee, U. S. Office of Civilian Defense, from 1943 to 1946, and of the California State War Problems Board, 1944-1946; since 1936 chairman of the American Institute of Pacific Relations; member of the National Executive Committee, Boy Scouts of America from 1939 to 1945 and member of the advisory council since 1945; chairman of the health committee of the Boys Clubs of America since 1940; president of Motion Pictures Research Council since 1935, and from 1939 to 1945 president of the California Physicians Service. He was a member of the Phi Beta Kappa and Sigma Xi societies, and since 1928 had been a director of Alpha Omega Alpha Honor Medical Society. He was the author of "Hoover Policies," 1937; "March of Medicine," 1938; "Human Hopes," addresses and papers on education, citizenship and social problems, 1940.

Dr. Ray Lyman Wilbur was recognized as a progressive thinker in the fields of education, medicine and statesmanship. His ability to speak forthrightly earned for him admiration and support. His philosophical observations, warmed by a tender humor, made him popular with public and press. Among great leaders in medicine of his generation his fame makes him among the greatest.

Ray Lyman Wilbur, M.D.

**Nejib George Barbour** ⊕ Brooklyn; University of Istanbul Medical Faculty, Turkey, 1889; died in Long Island College Hospital May 25, aged 83.

### New Treatment of Chronic Gastritis

H. Cattan and P. Frumusan (Tenon Hospital) propose a new method of treatment of chronic gastritis with synthetic antihistaminics. In a series of cases of chronic, edematous erosive gastritis, resistant to other treatments, 3277 R.P. (phenergan,® N-[2-dimethylamino-n-propyl] phenothiazine hydrochloride), taken in daily dose of 2 to 3 tablets of 0.025 Gm. before the two principal meals, procured a rapid and lasting recovery. Gastroscopic control showed the rapid disappearance of lesions. In a serious case, with continual cramp, vomiting, anorexia and emaciation in which gastroscopy has shown a stomach intolerant to air with hypersecretion and much edema, pains completely disappeared from the absorption of the first tablet of phenergan® (effect still lasting after five months). The appetite has returned, and loss of weight has stopped; the treatment lasted fifteen days only, and no functional sign of gastritis has reappeared. Gastroscopy has shown a normal mucosa. On March 14, 1949, at the same meeting of the society of gastroenterology, the authors reported a similar effect in edematous and painful esophagitis. Debray and Pergola have reported similar occurrences to the society of allergy. This often spectacular action of synthetic antihistaminics on gastritis is attributed by Cattan and Frumusan to the double pharmacodynamic effect of local anesthetic and modifier of the vascular permeability. Probably the first of those acts directly on the gastric mucosa, the almost immediate discontinuance of pains being compared to the effect obtained by the ingestion of procaine hydrochloride solutions. But, above all, it is by the diminution of the capillary permeability that phenergan® ought to act on the edema, an essential element of gastritis, whatever its cause. The authors consider that phenergan® is the most effective treatment of gastritis with predominance of hypersecretion and edema.

### Research on Recurrent Fever

Heretofore, it has not been possible to preserve in the laboratory, after an epidemic has subsided, a strain of Treponema recurrentis and, except for the monkey, no animal was considered sufficiently sensitive for its conservation. Thus, all experimental research was limited to the period of an epidemic. H. Baltazard, B. Seydian, Mofidi and Bahmanyar of the Iran Pasteur Institute have shown the high receptivity of newborn rodents. They chose the young rabbit, of a receptivity at least equal to that of the monkey, which has allowed them to keep a strain of T. recurrentis, R. XXIII, since May 31, 1947. Selected among the 15 strains isolated from human beings, the rest of which, after identification and some experiments, were left out in order to economize on rabbits, R. XXIII after 140 passages has retained all its characteristics: very weak pathogenicity for the white rat and the mouse, practically none for the guinea pig and the adult rabbit and very high pathogenicity for man, provoking violent and prolonged fits (confirmed by two contaminations in the laboratory). It has also been used for the pyretotherapy of patients with general paralysis; 25 subjects were inoculated after passages in the newborn rabbit or the louse from three and a half to twenty months after isolation. For the sake of security, all strains have been maintained by passage in the newborn rabbit every four or five days and also in lice infected on the rabbit. Research studies of 9 strains proved that every strain immunizes perfectly against itself, but does not immunize, or confers only a very weak resistance, against other strains; thus, the subject who has had epidemic recurrent fever is not immunized, as every new contamination will make him face a strain antigenically different than the first. The authors have brought to the fore a seasonal cycle in the virulence as regards man, a gradual abatement as from the end of the summer and the reappearance at the beginning of February of strains showing no modification in the newborn rabbit and the louse; this cycle depends, then, on biologic causes, similar to those admitted for most of epidemic infections. On the other hand, the authors confirmed the negative phase in the louse, described by Nicolle and his co-workers.

### Treatment of Infectious Anuria

Since the first case of anuria successfully treated by repeated "exsanguination transfusions" (Vallery-Radot, P.; Milliez; Laroche; Lhermitte, and Levasseur: *Bull. et mém. Soc. méd. d. hôp. de Paris* 65:908-915 [July] 1948) several similar observations have been published by (Tzanck and Dausset; Dérot, Tanret and their co-workers; Lian, Siguier, Crosnier, Savoie and Poullain). All these cases have been published in the *Bulletins et mémoires de la Société médicale des hôpitaux de Paris* in 1948 and 1949.

This method, which in France is usually called "méthode de Bessis," has been specially applied to the acute nephritis observed in septicemia due to Clostridium perfringens, a disease which seems more frequent in Europe than in the United States. Such a septicemia is generally controlled by penicillin, but this treatment does not prevent the development of anuria, which is considered the consequence of massive hemoglobinemia. Even when the blood cultures become negative soon after the beginning of the treatment, the anuria leads to death in nearly all cases. On the contrary, 5 cases have been published (and 2 unpublished have been observed by Pasteur Vallery-Radot and his co-workers) with cure obtained by the Bessis method: 5 to 8 liters of citrated blood are injected intravenously, and at the same time an equal quantity of blood is taken from the other arm. The operation is done once every day or once every other day, as long as the anuria persists (sixteen days in the first case published). The method can be supplemented by the use of an artificial kidney or by peritoneal irrigation.

### Compulsory BCG Vaccination

On April 8, 1949, the National Assembly passed a bill requiring antituberculous vaccination with BCG, save for recognized contraindications, for the following members of the population: (1) infants and babies staying with wet nurses, in crèches and day nurseries; (2) children living in the same home with a tuberculous person, receiving on this account prestations from the social security funds; (3) children of school age attending certain institutions; (4) students reading for physics, chemistry, biology, medicine and dentistry, student nurses, health visitors and midwives; (5) personnel of public and private health institutions, public administrations, commercial and industrial enterprizes and particularly persons working in unsanitary environments or handling foodstuffs; (6) soldiers, sailors and airmen. Persons coming under the bill will be vaccinated only if their skin reaction is negative, but babies might be vaccinated notwithstanding this. Persons over 30 years of age will not be subjected to compulsory vaccination. Vaccination will be carried out free of charge in centers organized by the Ministry for Public Health and Population, but persons affected by the law may be vaccinated at their own expense and they will be subject to control. Anybody who refuses to submit himself or the persons under his care or guardianship to the prescriptions of the law or interferes with its execution may be fined.

### Death of Félix d'Herelle

Félix d'Herelle died Feb. 22, 1949, at the age of 76. Born in Montreal, he received his B.A. degree in France, and pursued his medical studies in Canada. In 1901, he was promoted to professor of bacteriology in Guatemala and in 1908 in Mexico. From 1909 to 1921, he was associated with the Pasteur Institute, where, in 1917, he discovered the bacteriophage. In 1921, he was in Indo-China; from 1922 to 1923 he was "professeur extraordinaire" at Leyde University; from 1924 to 1925, he was a member of the maritime sanitary and quarantine council of Egypt. From 1928 to 1933, he was professor of protobiology at Yale University. Between 1934 and 1936, he founded Institutes of Bacteriophages at Kiev, Tiflis and Kharkov. Having had to leave Paris during the occupation, he returned in 1947; he attended the thirtieth commemoration of the discovery of the bacteriophage, organized by the Society of Microbiology at the Pasteur Institute. In November 1948, he was awarded, by the Academy of Sciences, one of the most important prizes: Petit d'Ormoy's Prize. He has been a great worker, endowed with great intelligence and intuition.

## BRAZIL

*(From Our Regular Correspondent)*

RIO DE JANEIRO, June 10, 1949.

### American Trypanosomiasis in Minas Gerais

American trypanosomiasis (Chagas' disease) is a rural endemic disease of the tropical and subtropical zones of the Americas, from Argentina and Chile to Mexico, a disease which is getting more and more important every day. In Brazil the Trypanosoma is known to exist at present in 12 of the 20 states, but the geographic distribution of the most important Triatoma vectors covers almost all the Brazilian territory. The disease in these cases, as a rule, is not diagnosed, or is labeled as some other disease, owing to the difficulty of the recognition of the acute disease and the lack of laboratory facilities in several states for blood cultures, inoculations and xenodiagnosis tests indispensable for the characterization of chronic disease. With an area of 227,000 square miles and a present population of 7,200,000, the state of Minas Gerais is one of the most important foci of trypanosomiasis in Brazil, as there are eight areas where cases have been repeatedly discovered. In a study of the prevalence of the disease in the state, Dr. J. Pellegrino, of the field staff of the Oswaldo Cruz Institute, and Dr. M. Borrotchin, of the Institute of Biology, University of Minas Gerais, investigated 181 unselected inmates of the Misericordia General Hospital of Bello Horizonte, to which patients come from surrounding rural districts. The 181 patients were subjected to a general examination and such special examinations as electrocardiography, complement fixation tests with Schizotrypanum cruzi culture antigen (Machado's reaction), Wassermann test, xenodiagnosis with Triatoma infestans nymphs, and chest radiography in patients with heart trouble of any kind.

Of the patients studied, 20.4 per cent had positive reactions to laboratory tests for Chagas' disease and 27.1 per cent had heart trouble with the following causes: American trypanosomiasis 18 cases; arteriosclerosis 13 cases; hypertension 12 cases; syphilis 6 cases; rheumatic fever 3 cases; congenital heart disease 1 case, and chronic cor pulmonale 1 case. Of the 37 patients with trypanosomiasis, 48.6 per cent showed evidence of myocardial damage. The most frequent electrocardiographic changes were right bundle branch block, ventricular premature beats, alterations of the QRS wave (single or associated to alterations of the T wave), auriculoventricular blocks. These findings are similar to those previously described in chronic Chagas' heart disease by Dias, Nobrega and Laranja. Exactly half of the patients with chronic trypanosomiasis were under 30 years of age, and 80.3 per cent of the patients with heart lesion from other causes than Chagas' disease were over 30 years. The complement fixation test proved to be very useful for the laboratory diagnosis of chronic Chagas' disease. The result of xenodiagnosis was positive in 8 out of 31 patients (25.8 per cent) with positive reactions to complement fixation tests.

The authors believe that trypanosomiasis is one of the most important factors of heart disease in the rural districts of Minas Gerais.

### The Work Against Plague

Plague is one of the principal public health problems of Brazil. It is endemic in a large section of the country, and a great number of cases still occur. The first chapter in the history of plague in Brazil began with the invasion in 1899 and ended in 1938, when the last scattered cases were registered in the southern part of the country (Rio de Janeiro and São Paulo). From 1939 to the present the disease has been reported only in the rural sections of the Northeast (the bulge: Piauhy, Ceará, Parahyba, Pernambuco, Alagoas, Sergipe and Bahia). From 1939 to 1943, 769 cases in human beings were registered (annual average 154). In the five years ending with 1948 the number of cases increased to 1,153 (annual average 231), including 386 in 1948. The bulk of last year's cases occurred in the interior of the state of Bahia (259 cases). The fatality rate is not high in Brazil and is decreasing progressively with the introduction of the sulfonamide drugs, complemented by the adequate use of vitaminic and antitoxic therapeutics. In 1934 the fatality rate was 33 per cent, and in 1947 and 1948 it was 13 per cent.

The Plague Division of the National Department of Health has 40 physicians, 40 laboratory technicians, 1,300 inspectors and the necessary personnel of clerical workers, drivers and helpers. The organization includes a central administrative and epidemiologic office in Rio de Janeiro and 26 field districts. In each district, with a local office and a field laboratory, a program of four main points is carried out: isolation and medical assistance of patients, rat destruction measures, ratproofing of dwellings and health education of the people. Besides its work in the 202 counties in the endemic region, the Plague Division is in charge of the defense of the harbors and cities. Among the recent improvements in the antiplague work is the use of avirulent live immunizing material instead of the old Haffkine type of vaccine.

The principal activities of the Plague Division during 1948 were: house inspections, 3,607,279; rat traps set, 6,600,470; doses of poison distributed, 10,817,287; applications of cyanogas, 6,707,705; applications of flame throwers, 283,796; applications of DDT, 3,823,977; rats destroyed, 2,516,029; ratproofing improvements enforced, 3,000,168; laboratory examinations, 902,827; rats classified, 855,764, and rats autopsied, 737,371.

### Institute of Malariology

An Institute of Malariology has been inaugurated at Sarapuhy, Rio de Janeiro, 20 miles from the boundary of the federal district, as a dependency of the Malaria Division of the National Department of Health. The Institute is composed of four sections: epidemiology, entomology, sanitary engineering and technical training of personnel. It is located in the coastal lowlands of Guanabara bay, where malaria is prevalent, and important engineering and medical activities against the disease are being carried out with great intensity. Dr. Lewis W. Hackett, Assistant Director of the International Health Division of the Rockefeller Foundation, delivered the address, emphasizing the importance of the creation of the Institute of Malariology. Dr. Hackett was the chief of an American technical mission which, twenty-five years ago, started the study of malaria problems in the same region where the Institute is now located.

# Correspondence

## INSTITUTE OF APPLIED BIOLOGY

*To the Editor:*—An article entitled "Cancer and the Need for Facts" that appeared in The Journal (January 8, p. 93) contained a number of unwarranted statements derogatory to the research of Dr. Emanuel Revici and the Institute of Applied Biology. These statements were based on a correspondence item published in The Journal on Aug. 18, 1945 (p. 1186).

We have in our possession and submit conclusive documentary evidence from a majority of these signers that completely contradicts their published unfavorable correspondence. Accordingly, the statements that appeared in The Journal were without justification if based on these alleged facts.

Such unwarranted propaganda against a research program on cancer carried on sincerely "not for profit" can only impede much needed progress in this difficult field.

The Institute of Applied Biology, 54 Greene Avenue, Brooklyn, is a non-profit, tax exempt membership corporation incorporated in April 1947, under the laws of the State of New York. It derives its support from voluntary contributions to the Cancer Research and Hospital Foundation which is composed of a group of prominent citizens of New York City. The Institute has as its objective the scientific and clinical investigation of the role of lipids in normal and abnormal cellular metabolism. Part of that program involves the study of the chemotherapeutic effect of lipids and various polar-nonpolar substances upon the course of the disease in patients suffering from cancer. The Institute accepts only cases in advanced stages of cancer, biopsy proven, which are no longer amenable to surgery, x-ray or radium. All patients are treated entirely without charge either for examination, treatment or medication.

Documented case histories and scientific data will be submitted by the staff of the Institute to appropriate journals for publication as the work progresses. The results thus far obtained demand continued investigation.

Abraham Ravich, M.D., Director,
Institute of Applied Biology, Inc., Brooklyn.

## "THE INTERNE"

*To the Editor:*—In the May 14 issue of The Journal there appeared a copy of a letter sent to the Association of Internes and Medical Students protesting the stand taken by its Convention on Health Insurance. It was prefaced by an editorial which can hardly be matched for its calumny and gross misstatement of facts.

The letter, the editorial stated, protested a recent statement, "made in *The Interne*, a magazine said to be the publication of the interns' organization." It continued, "Apparently this organization includes relatively few interns and residents but claims to represent them all."

*The Interne*, as can easily be ascertained by glancing at its cover, is the journal of the Association of Internes and Medical Students. The A.I.M.S. has never, and very obviously can never, claim to represent any but its own membership. It is possible that what has been confused is the fact that A.I.M.S. fights for the benefits of all interns and residents.

The editorial goes on to state, ". . . their [the authors of the letter] side of the story will not be published in *The Interne*." It must be immediately pointed out that it is a matter of A.I.M.S. policy to circulate all letters addressed to the organization among the members of the National Executive Committee before any action is taken. Significantly, a similar letter received from the Student Council of the University of Arkansas, that was addressed to the editor, is published with his answer in the June edition of *The Interne*.

*The Interne* through the years has opened its pages, though these are limited, to all points of view on controversial issues. In the field of health insurance, which is only one of its many interests, there have appeared articles by Dr. Frederick W. Williams of the National Physicians Committee and by Dr. Harvey B. Stone, Dr. Charles Austrian and Dr. Arthur M. Shipley. These men are all well known for their opposition to governmental health insurance schemes.

The A.I.M.S. in its conventions has had a similar policy. At every convention there have been speakers representing different points of view. At the last one, for example, Dr. James Miller, a member of the Board of Trustees of the American Medical Association, spoke in the seminar on Medical Care with Dr. Franz Goldmann of Harvard. A.I.M.S. chapters have always made it a principle to hold forum discussions on major problems. A good example is the William Welch chapter of Johns Hopkins where Dr. Bertrand Bernheim, Dr. Harvey Stone of the American Medical Association and Senator Murray spoke on Health Insurance.

This examination, though cursory, indicates the scientific objectivity with which the Association and its Journal have approached this important problem, which indeed is typical of their approach to all others. We, on the other hand, question whether your editorial was conceived in that same spirit. We feel that it is typical of the prejudiced, unscientific attitude which pervades the present "investigation" of the Association of Internes and Medical Students by the American Medical Association. Not once has the organization or any of its officers been called on to answer any of the charges made against it and in fact when a past A.I.M.S. president was in Chicago for that purpose he was not allowed to do so.

William Ruberman, M.D.,
Editor, *The Interne*.

## SEX DETERMINATION

*To the Editor:*—In reply to a request for an explanation of the fact (?) that the sex of the offspring is that of the relatively stronger parent, it was maintained in The Journal (May 28, 1949) that this has nothing to do with the determination of sex. The chromosomal explanation of sex determination was presented and the birth of about 94 females to every 100 males was cited as evidence in support of this explanation. However, approximately as many males as females would also be born if a number of factors besides the chromosomes influenced sex determination and under ordinary or uncontrolled conditions did so on a purely chance basis. As a matter of fact, human sex ratios have been reported which support the view that the sex of the offspring tends to be that of the "superior" parent. Thus, a ratio of 149 males to 100 females (5,676 males and 3,813 females) was reported by Seymour and Koerner (J. A. M. A. **116**:2747-2749 [June 21] 1941) to have resulted from artificial insemination in the United States and a ratio of 125 males to 100 females was found by Bernstein (*Science News Letter*, **55**:339, 1949) among children in 3,890 upper class families in the United States and Germany. It seems that these ratios may be due to relatively "superior" male parentage.

Similarly, in feeding and breeding tests with sheep and rats, evidence has been secured supporting the view that the sex of the offspring tends to be that of the better nourished parent. According to Geddes, P., and Thompson, J. A.: The Evolution of Sex, London, Williams & Norgate, 1904, Girou advanced this sex determination theory in 1828 on the basis of results obtained in breeding tests with a few sheep. Alexander Graham Bell (*J. Hered.* **5**:47, 1914) obtained evidence supporting Girou's theory by feeding and breeding tests on sheep, but further support of the theory was not obtained later when data were simply collected from farmers. Parkes and Drummond

(*Proc. Roy. Soc.*, London, s. B, 98: 147, 1925) found a high female ratio in offspring of female rats that were fed a diet adequate in vitamin B complex and were mated with males fed a diet deficient in vitamin B complex. Later, it became evident that the diets were deficient in vitamin E, but the fact remained that the female parents were the better fed parents and female offspring predominated. We (Hoelzel, Da Costa and Carlson, *Proc. Soc. Exper. Biol. & Med.* 40: 334, 1939) (preliminary report) mated rats fed diets differing in protein, vitamin B complex or vitamin E content and obtained evidence in short term tests that the principle involved in Girou's theory is a factor in sex determination. However, consistent results could not be obtained in long term tests. The study was discontinued after five years in which 1,428 litters of "nutritional hybrids," including 10,959 individuals, were obtained. It then seemed that a far more extended study than we were prepared to make would be needed to determine precisely how nutrition affects the sex ratio, but the chromosomal explanation of sex determination or pure chance did not appear to be sufficient to explain the results.

FREDERICK HOELZEL.
ANTON J. CARLSON, PH.D., M.D.
Department of Physiology, University of Chicago.

## DESOXYCORTICOSTERONE ACETATE NOT A SUBSTITUTE FOR COMPOUND E IN ARTHRITIS

*To the Editor:*—In a recent issue of THE JOURNAL (April 30, p. 1274) the work of the Mayo group dealing with the use of Kendall's compound E in the treatment of rheumatoid arthritis was cited and discussed. Shortly thereafter I learned of an instance in which desoxycorticosterone acetate was being used for the same purpose.

In a check on four leading pharmacists, one reported "many" purchases by physicians for use in cases of rheumatoid arthritis.

From our present knowledge of adrenal physiology, especially the work of Selye, the administration of desoxycorticosterone acetate in rheumatoid arthritis is to be condemned.

I feel that this matter should be stressed to prevent the possible widespread, improper use of desoxycorticosterone acetate.

LEO GITMAN, M.D., Brooklyn.

## ALBERT SCHWEITZER

*To the Editor:*—May I call your attention to some facts that illustrate relations among Albert Schweitzer, American history and current events.

I. The mission station Lambaréné was founded by Dr. Nassau in 1876. The evangelical mission in the Ogowe district began with the activity of American missionaries in 1874. In 1892 the colony Gabun became French. School lessons had to be held in the French language. Therefore the Paris missionary society took over. Robert Hamill Nassau was born in 1835 at Montgomery Square near Norristown, Pa.

He studied at Princeton Theological Seminary. In 1859 he asked the Presbyterian Board of Foreign Missions to send him to the most difficult and dangerous place. He received his medical degree from the University of Pennsylvania (1861). He translated the old testament and part of the new one into Benga, a native Negro language. He published "My Ogowe" and "The First Thirty Years of the West African Mission." He died at Ambler near Philadelphia in 1921. In his retirement, he received a letter from Schweitzer, who informed him that Lambaréné finally had a doctor again.

II. Albert Schweitzer was inspired by the Negro statue on the Marshfield in Colmar (part of the Bruat monument). "The sad expression of his face spoke to me about the sufferings of the native Negro in the dark continent." The sculptor of this statue is Fréderic Bartholdi, who also created the Statue of Liberty.

III. Schweitzer emphasized in his "Philosophy of Civilization" (two volumes) that one of the diseases of our time is the tendency to overorganization and commercial collectivism. He founded the hospital in Lambaréné even without the support of a missionary society. He financed it by his organ concerts and with the help of his friends. The Albert Schweitzer Fellowship (156 Fifth Avenue, New York 10) accepts contributions in this country.

WERNER K. GOTTSTEIN, M.D., Chicago.

# Council on Medical Education and Hospitals

## HAHNEMANN MEDICAL COLLEGE FULLY APPROVED

At its meeting on Friday, June 3, the Council on Medical Education and Hospitals of the American Medical Association voted to remove the Hahnemann Medical College of Philadelphia from probation and to restore the school to a status of full approval. This action was based on a detailed survey of the school carried out by the Secretary of the Council and a representative of the Association of American Medical Colleges, May 9-13, 1949.

This survey revealed that the deficiencies that were observed in 1945 and which led to the school's being placed on probation have been satisfactorily corrected. From the point of view of administration, curriculum, teaching staff, physical plant and clinical facilities, this school is now judged to be fully deserving of approval.

The Executive Council of the Association of American Medical Colleges has voted to recommend to the Association that it take similar action restoring the school to full approval at its meeting, Nov. 8, 1949.

DONALD G. ANDERSON, M.D., *Secretary*.

## PHYSICAL MEDICINE AND REHABILITATION

The Council on Medical Education and Hospitals has recently revised the Essentials for residency training in Physical Medicine and Rehabilitation. Hospitals conducting residencies limited to training in Physical Medicine are advised to expand their programs to meet the requirements of the broader concept of this specialty. A copy of the new Essentials as ratified by the House of Delegates June 6, 1949, follows:

Residencies in this specialty should include experience in the various aspects of rehabilitation and training in the clinical and diagnostic use of all physical agents except those employed in radiology. As used in these essentials, rehabilitative medicine is considered to be that phase of medicine which is concerned with the care, treatment and restoration of the physically and psychiatrically handicapped patient and of the convalescent. A complete program should include physical therapy, corrective speech, psychologic services, social service, occupational therapy, vocational guidance, education and planned recreation, correlated with the necessary medical, surgical and psychiatric care.[1]

A department of physical medicine and rehabilitation should be organized as a major service with a qualified department head and associates, as well as trained technical personnel. It should operate as a service department to the clinical divisions.

Sufficient space in the hospital and adequate equipment should be provided to carry out a comprehensive and well planned program. The allocation to this service of a sufficient number of beds, as well as treatment rooms, offices, class rooms and space for recreation and other activities, is highly advantageous, if not essential.

---

[1] Programs presently limited to training in physical medicine should be expanded to meet the requirements of the broader concept of this specialty.

A minimum of three years of residency training is considered necessary to train a physician who desires to specialize in this field. Shorter training periods in this specialty of from six to twelve months may be valuable for residents in medicine, surgery and other specialties.

A three year program should encompass the entire field of physical medicine, including its basic science aspects: medicine, in the rehabilitative aspects of arthritic, cardiovascular and other chronic diseases; ophthalmology-otolaryngology, in the rehabilitation of the blind, deaf and otherwise handicapped patient; psychiatry, as it applies to the care and treatment of the convalescent medical and surgical patient and the psychoneurotic patient; neurology, particularly in its application to special problems such as hemiplegia and other chronic neurologic disorders; orthopedics, as it applies to congenital and acquired deformities; surgery, as it applies to traumatic, amputee and plastic cases; and pediatrics in its relation to the poliomyelitic, rheumatic, cerebral palsied and similar patients. Theoretical and practical training should be given in the use of braces and prosthetic appliances, special technics and equipment for the evaluation, diagnosis and treatment of the physically and mentally handicapped. Psychosocial and prevocational rehabilitation of the convalescent and chronically ill patient should be an integral part of the program. In those cases where the outpatient activity is limited, affiliation with other institutions offering training in special aspects of this field is indicated.

### QUANTITATIVE REQUIREMENTS

To supply an adequate amount and variety of teaching material, there should be a minimum of 500 admissions and 7,500 patient visits to the department annually.

### APPLIED BASIC SCIENCE INSTRUCTION

Training at the graduate level in anatomy, physiology, physics, biophysics and pathology is considered essential. The training in anatomy should include functional anatomy and kinesiology. The training in physics should include radiation physics, electronics and instrumentation. Study in applied basic sciences should be closely correlated with clinical experience.

### BOARD REQUIREMENTS

The American Board of Physical Medicine requires candidates for the certifying examination to have completed an approved rotating internship, following graduation from a medical school approved by the Council on Medical Education and Hospitals, a period of study after the internship of not less than three years of approved supervised training and not less than two additional years of study and/or practice in this specialty.

The Board requires that the special training following the internship include a period of study in clinics, dispensaries or hospitals recognized by the Council on Medical Education and Hospitals and by the American Board of Physical Medicine as competent to provide a satisfactory training in physical medicine and rehabilitation. During this period, the resident should be assigned directly to the department of physical medicine and rehabilitation for a minimum of one and one half years. The period of specialized preparation should include (*a*) graduate training in anatomy, including kinesiology and functional anatomy; physics, including radiation physics, electronics and medical instrumentation; physiology; pathology, and other basic sciences which are necessary to the proper understanding of the specialty; (*b*) an active experience of not less than two years in hospitals, clinics or dispensaries approved by the Council and the American Board of Physical Medicine. An additional period of not less than two years of study and/or practice in the specialty is considered necessary to complete the applicant's training. The candidate is required to pass a written and oral examination given by the Board, which will include questions concerning the basic sciences, clinical practice and laboratory and public health problems related to physical medicine and rehabilitation.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. Sept. 12-14. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc. *Written.* Various Centers. July 15. *Oral.* Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

American Board of Internal Medicine: *Written.* Oct. 17. Asst. Sec.-Treas. Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Obstetrics and Gynecology, Inc. *Part I.* Various Centers. Feb. 3. Final date for filing application is Nov. 5. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Ophthalmology: St. Louis, Oct. 15-19; Boston, December. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery. *Part II,* New York City, Feb. 9-10. Final date for filing application for Part II is Aug. 15. Address: Sec.-Treas., Dr. Harold A. Sofield, Room 1856, 122 S. Michigan Ave., Chicago.

American Board of Otolaryngology: Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Chicago, Oct. 7-8. Final date for filing application is Sept. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: *Oral.* Cleveland, Sept. 16-18; New York City, Oct. 21-23; Chicago, Dec. 9-11. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Preventive Medicine and Public Health: *Parts I and II.* New York, Oct. 22-24. Final date for filing application is July 22. Sec., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore.

American Board of Psychiatry and Neurology, Inc. *Special Examination,* Chicago, Oct. 24-25. Final date for filing application is July 15. December, New York City. Sec. Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, October 26. Final date for filing applications is July 1. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: *Written.* December. *Oral and Clinical.* Chicago, Feb. 11-15. Final date for receipt of case histories is Sept. 1, 1949. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18.

ALASKA: Juneau, Aug. 28. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

ARKANSAS: *Examination.* Little Rock, Oct. 4. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

DISTRICT OF COLUMBIA: Washington, Oct. 24-25. Sec., Dr. G. C. Ruhland, 4130 E. Municipal Bldg., Washington.

FLORIDA: *Examination.* Gainesville, Nov. 5. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

IOWA: Des Moines, July 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

MICHIGAN: *Examination.* Detroit and Ann Arbor, Oct. 14-15. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing 15.

NEBRASKA: Omaha, Oct. 4-5. Director, Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln 9.

OREGON: Portland, Sept. 3 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

RHODE ISLAND: *Examination.* Providence, Aug. 10. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

WASHINGTON: Seattle, July 13-14. Sec., Department of Licenses, Mr. Edward C. Dohm, Olympia.

WISCONSIN: Milwaukee, Sept. 24 and Dec 3. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Bureau of Legal Medicine and Legislation

## MEDICOLEGAL ABSTRACTS

**Physical Examinations: Defendant Physician's Right to Examination of Plaintiff in Malpractice Action.**—The plaintiff filed suit for damages caused by the alleged malpractice of the defendant physician during the course of a physical examination. A trial held before a jury resulted in a verdict in favor of the plaintiff, on which judgment was entered, so the defendant physician appealed to the appellate court of Indiana.

The plaintiff alleged, in substance, that she consulted the defendant, a duly licensed and practicing physician and surgeon, for the purpose of having him diagnose the cause of a rash or skin eruption on her neck and chest; that in the course of this examination he ruptured her hymen by means of a bivalve speculum; that the defendant was negligent, careless and failed to exercise the degree of care and skill required in the making of such examination and in the rupture of the hymen. Prior to trial the defendant filed a petition asking the court to require the plaintiff to submit to a physical examination. In this petition the defendant alleged that the plaintiff could be examined, without harm or pain to herself, by a physician who is a specialist, that since the very character of the plaintiff's cause of action involves intimate information concerning the plaintiff's person she cannot be embarrassed by a physical examination and the same would not constitute an invasion of the privacy of the plaintiff's person; that a refusal by the court to have a professional disinterested physician witness examine the plaintiff as to the contentions in her complaint and discover the present conditions, concerning which the plaintiff has made allegations and concerning which she will testify, will so prevent the defendant from obtaining information concerning the very subject matter of this action as to constitute an abuse of the right of the defendant to have investigated the facts concerning which only the plaintiff can otherwise have knowledge and will prevent the defendant from interposing a full defense in this action. The court overruled this petition and, on appeal, the defendant contended that the trial court erred in so doing for the reason that the alleged injury and the nature and extent thereof could be discerned only by objective findings of expert medical examiners, and that such examination could have been made without danger, pain, harm, injury or embarrassment to the plaintiff. The plaintiff, on the other hand, contended that the question of whether such a motion should be granted was discretionary with the trial court and that in this case there was no abuse of such discretion.

The leading case on the question, said the appellate court, is *City of South Bend et al v. Turner, 156 Indiana, 418.* In that case the trial court denied the motion of the appellant for a physical examination of appellee to determine the true character and extent of his injuries and their probable effect as to permanancy on his mind and person. In reversing the trial judgment, the Supreme Court of Indiana reviewed the decisions of many jurisdictions, concluded that the great majority uphold the right of courts to require an examination in proper circumstances and set forth the following propositions which the cases establish: (1) That trial courts have the power to order the medical examination by experts of the injured parts of a plaintiff who is seeking to recover damages therefor; (2) that a defendant has no absolute right to demand the enforcement of such order, but the motion therefor is addressed to the sound discretion of the trial court; (3) that the exercise of such discretion is reviewable on appeal, and correctible in cases of abuse; (4) that the examination should be applied for and made before entering on the trial, and should be ordered and conducted under the direction of the court, whenever it fairly appears that the ends of justice require a more certain ascertainment of important facts which can only be disclosed or fully elucidated by such an examination, and such an examination may be made without danger to the plaintiff's life or health or the infliction of serious pain; (5) that the refusal of the motion when the circumstances appearing in the record present a reasonably clear case for the examination, under the rules stated, is such an abuse of discretion in the trial court as will operate to reverse a judgment for the plaintiff; (6) that such order may be enforced, not by punishment as for a contempt, but by delaying or dismissing the proceeding. "When it becomes a question of probable violence to the refined and delicate feelings of the plaintiff, on the one hand, and probable injustice to the defendant, on the other, the law will not hesitate . . ." concluded the court in the South Bend case.

While the injuries are of a different nature in the instant case, said the appellate court, we believe that the principles which guided that decision apply with equal and perhaps greater force here. The defendant's motion was seasonably made, and it was incumbent on the plaintiff to produce evidence as to the nature and extent of the rupture and whether or not it caused in whole or in part a destruction of her hymen. These facts could be established only through a physical examination by competent physicians. Such an examination could be made without danger to her life or health and without infliction of serious pain. Certainly, continued the court, it cannot be seriously maintained that such an examination would be an invasion of her privacy or would cause her such embarrassment as to justify the denial of the motion, because in order to maintain her case she would be required to testify as to the details of the examination out of which this action arose. The denial of the motion for a physical examination of the plaintiff deprived the defendant and the court of the best method of determining the nature and extent of the plaintiff's alleged injuries. This was a reversible error, concluded the court.

The judgment of the trial court in favor of the plaintiff was accordingly reversed and an order entered granting the defendant's motion for a physical examination.—*Templin v. Erkekedis, 84 N. E. (2d) 728 (Ind., 1949).*

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. *Requests should be accompanied by stamps* to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Electrocardiogram in Ventricular Aneurysm.* B. Rosenberg and W. J. Messinger.—p. 267.

**Quinacrine Hydrochloride in Cardiac Arrhythmias.**—Gertler and Yohalem report observations on 32 patients who were hospitalized with cardiac arrhythmias and treated with quinacrine hydrochloride. The dosage varied from 0.3 to 0.6 Gm., intramuscularly, in the first 9 cases; in all but 2 of the remaining cases 0.4 Gm. was given intramuscularly. All injections were administered in the gluteal region, the quinacrine hydrochloride being dissolved in 10 cc. of 1 per cent procaine hydrochloride solution. The quinacrine hydrochloride was used in twenty-seven trials in 26 patients with auricular fibrillation. In 13 of these the results were satisfactory. Among the 14 patients in whom treatment with quinacrine hydrochloride was unsuccessful, there were 5 with thyrotoxic heart disease and 1 with fatal pheochromocytoma with rheumatic heart disease. Quinidine, administered before quinacrine hydrochloride was used, was ineffective in sixteen trials. In patients in whom quinacrine hydrochloride failed to restore a normal rhythm digitalis and/or quinidine was of no avail in all but one instance. Six patients with cardiac arrhythmias other than auricular fibrillation were treated with quinacrine hydrochloride; included were 2 cases each of nodal tachycardia, auricular flutter and ventricular tachycardia. Quinacrine hydrochloride was successful in 3 of these 6 cases; 2 of the unsuccessfully treated patients died shortly after treatment, and revealed coronary occlusion. The best results of quinacrine hydrochloride occurred in older patients with arteriosclerotic cardiovascular disease and in younger patients in whom the arrhythmia was of less than forty-eight hours' duration. The time at which the arrhythmias disappeared after therapy with quinacrine hydrochloride approximated the time at which the maximal blood levels were reached after intramuscular injections.

*Experimental Production and Treatment of Peptic Ulcers: Review of Literature.* M. Berg.—p. 35.
Trends in Diagnosis, Etiology and Treatment of Duodenal Ulcer. F. G. Connell.—p. 55.
*Soil, Food and Health. N. P. Norman.—p. 63.

**Soil, Food and Health.**—Norman stresses that fertile soils, healthy plants and healthy animals constitute our most potent apparatus for the maintenance of health and the prevention of most diseases. He deplores that even now, despite the numerous positive findings of nutritional research, the rank and file of physicians and dentists ignore the enormous therapeutic potential which is inherent in foods of good biologic value. The author feels that the modern food processing industry is responsible for much malnutrition. Physicians should interest themselves in the soil; its fertility, its replenishment and conservation. They should educate the people to insist on buying natural foods rich in nutritive essentials and to refuse to buy highly processed food commodities. Food of good biologic value is the best therapeutic agent we possess.

### American Journal of Medicine, New York

**6**:139-274 (Feb.) 1949

*Multiple Myeloma: Its Clinical and Laboratory Diagnosis with Emphasis on Electrophoretic Abnormalities. W. S. Adams, E. L. Alling and J. S. Lawrence.—p. 141.
*Test for Presence of "Hypertensive Diencephalic Syndrome" Using Histamine. H. A. Schroeder and M. L. Goldman.—p. 162.
*Treatment of Thromboangiitis Obliterans: Two-Year Follow-Up After* Sympathectomy. W. J. Messinger, E. N. Goodman and J. C. White. —p. 168.
Consideration of Glomerular Nephritis in Its Relation to Sulfonamide Sensitivity. R. H. Rigdon, W. H. Siddon and D. E. Fletcher.—p. 177.
*Chemotherapy of Malignant Disease.* A. Gellhorn and L. O. Jones. —p. 188.
Role of Cardiac Output in Mechanisms of Congestive Heart Failure. E. A. Stead Jr.—p. 232.

**Multiple Myeloma.**—Adams and his co-workers report 61 cases of multiple myeloma in 44 men and 17 women between the ages of 31 and 76, the average in this group being 58 years. Sixty patients showed a pronounced carious condition or a complete absence of teeth, suggesting that the same process which so commonly leads to skeletal osteoporosis also affects the teeth. Forty-one patients had bone pain and as many patients had loss of weight. Thirty-seven patients had gastrointestinal symptoms and 31 had low grade, remittent fever. Pallor was present in 28 patients. Bleeding occurred in 24 patients. Disorders of the nervous system were observed in 21 patients, root cord compression being the commonest neurologic manifestation. Bone tumors were present in 13 patients. The incidence of Bence Jones proteinuria was 28. Elevated total plasma protein occurred in 31 cases. Hyperglobulinemia was present in 41 cases. Because of a lowered albumin level hyperglobulinemia may be present without hyperproteinemia. Electrophoretic studies were made in 29 cases; in 15 of them the electrophoretic patterns were similar to those previously reported. In 6 cases there was a tall, narrow, abnormal peak migrating more slowly than gamma globulin, a type of pattern which has not been previously reported. In 8 cases large abnormal peaks were absent, but there were significant small abnormalities; in these 8 cases the incidence of Bence Jones proteinuria was 87.5 per cent, suggesting that in many cases in which large abnormal peaks are absent, small abnormalities are due to Bence Jones protein in the plasma. The high incidence of Bence Jones proteinuria in this group may result from the absence in the plasma of a high molecular weight protein capable of forming complexes with Bence Jones protein. The accuracy and promptness of the diagnosis of multiple myeloma may be increased by careful electrophoretic studies and by greater attention to the occurrence of rouleaux formation of the red blood cells in the peripheral blood (observed in 36 of the authors' cases) and to the bright blue coloration of the Wright's stained blood smear. Any case of unexplained anemia should be given the benefit of a sternal aspiration and/or sternal biopsy. Energetic search should be made for Bence Jones protein. Serum calcium level, inorganic phosphorus, alkaline and acid phosphatase should be determined. Careful analysis of all roentgenographic osteolytic processes should be made, and more attention should be paid to the occurrence of osteoporosis.

**Histamine Test.**—Schroeder and Goldman performed a test using the intradermal injection of 0.25 mg. of histamine on 103 ward and clinic patients, 53 of whom had arterial hypertension and 50 did not. Of the hypertensive patients 16 were men and 37 were women; there were 25 normotensive men and 25 women. Criteria such as flushing of the face and circumoral pallor, headache, lacrimation, blotchy erythema on the face, back, neckline, chest and abdomen and local reaction at the site of injection were graded 1 plus to 4 plus. Sixteen hypertensive patients showed a reaction to histamine considered as 3 or 4 plus. All were considered to exhibit clinical signs of "neurogenic" hypertension in that blood pressures were labile, vascular disease was minimal, the course was usually benign and there were associated emotional disturbances. Sixteen more patients of a similar type gave a reaction considered as 2 plus, a definite although less marked response. Only 7 of this type did not react or reacted only slightly. Of the normal controls 40 patients did not react in this manner to histamine, 5 reacted slightly and only 5 showed responses considered 2 to 4 plus; 2 of these suffered from psychoneurosis, 1 from Hodgkin's disease and 1 from mild rheumatoid arthritis. Tests were repeated weeks or months apart in 6 patients who reacted, and similar results were obtained. Attacks simulating presenting symptoms were initiated by histamine in most of those patients in whom the reaction was positive. In addition to the blush and headache, symptoms included severe spells of weeping, dizziness, palpitation, excitement and anxiety, and tachycardia. Histamine-like substances may be concerned in the causation of some of the symptoms typical of the "hypertensive diencephalic syndrome" which are common to many hypertensive patients, especially those exhibiting the "neurogenic" type.

**Malignant Tumors of Uterine Fundus Subsequent to Irradiation.**—Speert and Peightal point out that exposure of the female genital organs to radiant energy in the form of roentgen rays or radium emanations may not be as innocuous as it has long been believed to be. At least 21 of the 270 patients (8 per cent) who have been treated for malignant tumors of the uterine fundus on the gynecologic service of the Roosevelt Hospital have had previous pelvic irradiation for benign conditions. The incidence of previous pelvic irradiation among patients with cervical carcinoma, by contrast, was only 0.3 per cent. The important clinical question is whether pelvic irradiation influences the subsequent development of neoplastic disease of the uterine fundus. Six of the 21 tumors contained sarcomatous elements. This was five times the incidence of sarcomas among all the malignant tumors of the uterine fundus. The average time interval between irradiation and detection of the uterine cancers was 8.3 years. These findings, together with previously published data in the literature, suggest a possible carcinogenic effect of radiant energy on the human uterine fundus.

**Pregnancy and Hodgkin's Disease.**—Kasdon says that 3 patients with Hodgkin's lymphogranulomatosis, who were pregnant, were treated in the tumor clinic of the Boston Dispensary in the past ten years. A total of 12 women with Hodgkin's disease were admitted during this period. Each diagnosis was confirmed by histologic study. An analysis of earlier reports together with these 3 cases is considered to be of some value in developing a basis for the management of the obstetric factors in this complex situation. The author arrives at the conclusion that Hodgkin's disease complicating pregnancy does not grossly affect ovulation, fertility, incidence of spontaneous abortion or of hemorrhage before, during or after parturition. Gestation, parturition and the puerperium are not affected by coincidental Hodgkin's disease, but the disease is transmitted from the mother to the fetus across the placenta in 9 per cent of the reported cases. There is no report in the literature of injury to the shielded fetus from roentgen radiation used in the treatment of Hodgkin's disease. Interruption of pregnancy during the course of Hodgkin's disease is not indicated from the evidence at hand.

Arctic Sanitation. W. A. Hardenbergh.—p. 202.

**Home Care Program.**—Cherkasky states that hospitals, despite their stress on scientific medicine, diagnostic apparatus, laboratory examination and therapeutic procedures, have held back from an understanding of sick human beings as social human beings. Montefiore Hospital, in extending its services into the home, has begun to learn many things about the patient which can only be learned when he is in the bosom of his family. To the doctors on the program it has brought a new realization of the importance of social factors in disease. Certain questions must be answered before it can be decided that it is best for a patient to return to his home. Some families seem not to want the patient back, but closer investigation reveals that the reason is not lack of love, but fear—fear of illness, fear of impending disaster, fear of inability to do what is required. If the fundamental attitudes are sound, all these fears can be overcome. When it has been decided that a patient is medically and socially eligible, the patient goes on home care and receives medical services including specialists. Social service, visiting nurses' service and housekeeping services are provided, as are transportation, medication and occupational and physical therapy. Home care for patients who are suitable is not only "as good as" hospital care—it is infinitely better. The author cites a case to illustrate the advantages of the home care program.

**Survival of Influenza Virus Between Epidemics.**—Taylor says that a search for influenza virus in an institutional population during the fall, winter and spring months revealed the presence of virus in the throats of symptomless persons thirty-two days before a clinically manifest epidemic and during the epidemic but not on other occasions. All save one strain isolated from influenza suspects in 1947 and 1948, as well as the strains isolated from the throats of symptomless persons shortly before and during the epidemic of 1947, are antigenically similar. While they may be regarded as belonging to type A influenza virus, they differ markedly from PR8 and an A type virus isolated in 1943. There was no significant difference in the influenza attack rate among persons vaccinated with a commercial A and B type influenza vaccine four months before an institutional epidemic in 1947 and among those who were not vaccinated.

**Bleeding Following Tonsillectomy.**—Fox and West differentiate between primary and secondary hemorrhage. Primary bleeding occurs during the first twenty-four to forty-eight hours postoperatively, while secondary bleeding occurs thereafter and up to ten days postoperatively. Primary bleeding is due to inadequate surgical hemostasis at the time of operation, or occasionally to the loss of a ligature from the throat during the reaction period. Predisposing factors and causes for secondary hemorrhage include acute febrile diseases occurring during convalescence; dietary deficiences, particularly of vitamins and proteins; hypertension; local infection; local trauma; blood dyscrasias, and certain drugs. The authors review a series of 687 cases of tonsillectomy and adenoidectomy to show the effects of acetylsalicylic acid chewing gum and vitamin K on secondary tonsillar bleeding. It is felt that the local use of acetylsalicylic acid is a major factor in late tonsillar bleeding and should therefore be avoided.

**Use of Human Centrifuge in Studies on Headaches.**—The observations presented by Kunkle and his associates concern the effects of centrifugal forces on certain experimentally induced and clinical headaches. They found that the exposure to a positive acceleration of 3.0 or 4.0 g (centrifugal forces in the head to seat direction) on the human centrifuge had little or no effect on the pain threshold to the stimulus of radiant heat or on the intensity of pain induced by a variety of stimuli. Experimentally induced headaches of nonvascular origin arising from compression or irritation of the surface tissues of the head were only slightly reduced in intensity during exposure to a positive acceleration of 3.0 g; the minor changes in such headaches were attributable to distraction. Experimentally induced headaches of moderate severity arising from distention of cranial arteries (histamine and caffeine withdrawal headaches) were eliminated during exposure to positive accelerations of 2.0 or 3.0 g, a relief attributable to a concurrent fall in intravascular pressure at the head level. Clinical headaches of vascular origin responded similarly, for in subjects experiencing headache related to hunger, recent head trauma or emotional tension, all with clinical features suggesting that the pain arose from distention of intracranial or extracranial arteries, the headache was completely eliminated during exposure to a positive acceleration of 2.0 g. A brief headache was sometimes noted in the normal subject during release from increased positive g; such headache probably arises from transient distention of cranial arteries, and in this respect is the analogue of headache induced by negative g. The human centrifuge is a useful tool in the analysis of vascular mechanisms in headache.

**Effect of Pregnancy on Otosclerosis.**—Smith cites reports from the literature that indicate that pregnancy may cause an increase in hearing loss in patients with otosclerosis. The incidence of this pregnancy-connected hearing loss in women with otosclerosis varies from 20 to over 70 per cent in the reports cited. The author made a study of 73 cases observed at the New York Eye and Ear Infirmary. His survey was restricted to cases in which after full examination the patient had been judged a suitable candidate for the operation. He found that the onset of hearing loss was initiated by pregnancy in 22.9 per cent of the 73 patients studied, and it was further increased by pregnancy in an additional 14.7 per cent. The evidence in the literature reviewed and the results of the study presented agree that eugenic measures are ineffective in the prophylaxis of otosclerosis. Hearing aids and fenestration of the labyrinth may offer relief to patients afflicted with otosclerosis. Abortion and sterilization are not indicated in the average case of otosclerosis complicated with pregnancy.

**Streptomycin in Tuberculosis of Ear, Nose and Throat.**—Greif and Gould report 12 cases of tuberculosis of the ear, the nose or the throat treated with streptomycin at Fitzsimons General Hospital, Denver. Apparent healing was obtained in 4 of 6 patients with tuberculosis of the larynx, in 1 patient with tuberculosis of pharynx and larynx; in 2 of 3 patients with tuberculosis of the middle ear and in 1 patient with tuberculosis of the mastoid process. Improvement was observed in 2 patients with tuberculosis of the larynx and in 1 patient with tuberculosis of the nasal septum. There was no improvement in 1 patient with tuberculosis of the middle ear.

**Thyroidectomy and the Parathyroids.**—*Johnstone* and *Voth-Ostendorph* direct attention to the fact that although the dire consequences of injury to the parathyroids or of removal of the glands are generally appreciated, thyroidectomies are done often without the operator's being able to recognize this tissue. As a test to determine the difficulty in recognition of parathyroid tissue, 248 specimens were obtained of what was judged to be parathyroid tissue from 100 postmortem examinations and submitted for microscopic examination by the pathologist. One hundred and ninety-one specimens proved to be parathyroid tissue, 32 were lymph nodes and 25 were thyroid gland. The incidence of recognition was 77 per cent. The most common location of a parathyroid gland was found to be at the crossroads of the inferior thyroid artery and the recurrent laryngeal nerve. The next most common place was near the lower pole of the thyroid gland. In 100 reports on operations on the thyroid, 7 described visualization of parathyroid glands, one stated that no parathyroid glands were seen and 92 made no statement in regard to the presence or absence of the parathyroids. The authors feel that the recognition of the parathyroids during thyroidectomy is essential and that the best way of acquiring skill in recognizing them is by dissection at necropsy.

**Cabbage Juice for Peptic Ulcer.**—Cheney describes observations on 13 patients with peptic ulcer who were treated with cabbage juice. Experiments indicate that this juice contains an antipeptic ulcer factor (vitamin U), which prevents the development of histamine-induced ulcers in guinea pigs. Since computations on animals suggested that a patient would require about 720 cc. of this juice daily, it was decided to give 1,000 cc. daily, but occasionally patients took only 500 or 600 cc. daily for a day or two until they became used to this beverage. Fresh juice was prepared by means of a juice press twice daily. About 2 Kg. of cabbage were required to produce 1,000 cc. of juice. Since an addition of celery juice made the beverage more palatable and since celery was known to contain the antipeptic ulcer factor, 25 per cent of celery juice was mixed with 75 per cent of cabbage juice. The juice was given five times daily in doses of 200 cc. each. The average period required for the healing of the crater was 10.4 days in the 7 patients with duodenal ulcer, and 7.3 days in the 6 patients with gastric ulcer. The rapid healing of peptic ulcer after treatment with cabbage juice suggests that a deficiency in a dietary factor may play a part in the genesis of peptic ulcer.

**Radiation Therapy in Peptic Ulcer.**—Ricketts and his associates analyze the results of roentgen irradiation of the fundus and corpus of the stomach in more than 800 cases of peptic ulcer studied from 1936 to 1947. Four different technics were used, but the kilovoltage, filtration, etc., remained the same. The authors feel that because of the variation in the position of the stomach, it would have been advisable to determine fluoroscopically the exact position of the gastric fundus and corpus prior to the irradiation, thus avoiding unnecessary radiation of other tissues and insuring radiation of the desired areas. However, this precaution was not taken in the majority of these cases, the radiation being directed at a location found to be the usual position of the stomach. This error may account for some of the failures; fluoroscopic control is now routine. It was possible to follow the course of 423 patients. There were indications of a direct correlation between depression of gastric secretion and healing of the ulcer. In each of 44 patients with achlorhydria persisting for three months or longer the ulcer healed completely. When irradiation is delivered to the acid-secreting portions of the mucosa, all phases of secretion, chemical, cephalic and intestinal, are depressed as a result of direct cellular injury. Individual variations occur in patients receiving the same amount of radiation, corroborating the view that the result depends not merely on the amount of radiation given, but also on the variable and unpredictable tissue susceptibility. Statistically, the effect varies in direct proportion to the amount given, other factors being equal. There is a higher incidence of postradiation achlorhydria in patients with gastric ulcer than in those with duodenal or jejunal ulcer. The achlorhydria varies in duration from a few days to as long as eight years. Ulcer pain disappears during achlorhydria. Irradiation achlorhydria does not produce symptoms. Recurrence of the ulcer is preceded by reappearance of acid gastric secretion. The incidence of recurrence is definitely lowered by irradiation.

**Radiation Therapy in Selected Cases of Peptic Ulcer.**—Having observed that roentgen irradiation exerts a variable and unpredictable effect on gastric secretion, Ricketts and his co-workers decided to supplement their statistical analysis with a description of some of the more dramatic results and a consideration of some of the failures. The authors present the histories of 3 patients with gastric ulcer. The first one had a long history of ulcer distress until radiation therapy produced prolonged achlorhydria and a dramatic cure of the ulcer. Radiation effected healing of the ulcer likewise in the other 2 patients with gastric ulcer. There were 5 among 50 patients with gastric ulcer in whom healing was not produced by treatment for one month or more with the standard medical antacid regimen and roentgen irradiation. The authors present the case records of 3 patients with duodenal ulcer in whom irradiation produced reduction in gastric secretion and healing of the ulcer. Relatively few cases of jejunal ulcer have been subjected to radiation therapy. The results have often seemed surprisingly good, but the incidence of ultimate recurrence has been high. The authors feel that the ultimate value of radiation therapy in peptic ulcer and its ultimate effect on the gastric mucosa have yet to be determined.

Attitudes and Activities of the Middle-Aged and Aged. L. Pearl Gardner.—p. 33.

**Reduction of Surgical Risk.**—According to Bisgard, every detail in the surgical management of elderly patients, beginning with the history and physical examination and including the anesthesia and preoperative and postoperative care, must be painstakingly carried out. In this age group there is a greater need of team work between the surgeon, internists and other specialists. Preliminary examination should include an estimate of the functional capacity of the cardiovascular and renal systems. There is great need of complete preoperative rehabilitation. Protein deficiency should be corrected preoperatively and prevented postoperatively by supplying of protein in excess of the normal daily requirement of about 1 Gm. of protein for each kilogram of body weight, that is 50 to 100 Gm. Replacement is best accomplished by the oral route, but often this is not possible and one must resort to the parenteral administration of plasma and amino acid mixtures. The elderly patients should be maintained in relative water and electrolyte balance, but particular attention must be exercised to avoid overhydration. If there is any evidence of impaired renal function, lactated Ringer's solution should be used in place of isotonic sodium chloride solution. There is pressing need for transfusions to replace blood loss and to maintain normal blood values. Acute cholecystitis and internal hemorrhage present specific problems in the elderly. Immediate or early cholecystectomy or drainage should be done. Because of arteriosclerosis hemorrhage is more likely to continue to exsanguination so that its management demands more radical treatment.

*Value of Early Recognition and Early Therapy in Cerebral Palsy. Margaret Watkins.—p. 48.
*Rational Use of Estrogens. Chloe O. Fry.—p. 51.
Diabetes Today. Priscilla White.—p. 55.

**Cerebral Palsy.**—According to Watkins cerebral palsy is widespread, for each year there are born 7 per hundred thousand population. Of these 7, 1 will die in infancy and 2 will be feebleminded, leaving 4 who are treatable or educable. Of these 4, the condition of 1 will be severe, of 2 moderate and of 1 mild. The physician should see that the children with this condition are directed to a center where they can be given the proper therapy, the proper education and instruction. It should be remembered that because of impairment of the neuromuscular system these children do not do automatically those things which they should do, but can be taught a different type of muscle control by early training in good patterns of behavior before bad habits are established. The treatment is a combination of physical therapy, occupational therapy and speech therapy. As soon as cerebral palsy is recognized the baby should be started on conditioned exercises. The parents are taught exercises to be given while a simple rhyme is sung; in other words, conditioned response based on Pavlov's experiments. Through constant repetition of the rhyme and the exercise, passive motion is changed to active assisted motion and finally to active motion. The exercises are designed to teach reciprocation of the legs and reach and grasp of the arms and hands.

**The Rational Use of Estrogens.**—Fry is of the opinion that the administration of estrogen "shots" has become a lucrative racket for some who readily attribute symptoms in women between 30 and 60 to the menopause. When used rationally, estrogens do improve well-being, but they are also potentially dangerous. The author discusses the type of estrogen available, the dosage and the mode of administration. She believes that during the menopause the oral route is preferable. Senile or atrophic vaginitis is treated by the nightly introduction into the vagina of a suppository containing estrogen. The estrogen should be discontinued in a month and repeated only if symptoms recur. Some cases of functional dysmenorrhea are dramatically helped by the rational administration of estrogens. The treatment of functional excesses of uterine bleeding is simple and satisfactory since the advent of estrogens and progesterone. The author also comments on the use of hormones in sterility, in the treatment of pregnant diabetic women and in the toxemias of pregnancy. She warns against the abuse of estrogens. She stresses that they should not be given: to anyone who has endometriosis, to the premenopausal woman for irregular periods, to anyone with a family history of carcinoma, to a patient who exhibits or who has had a fibroadenoma of the breast, to anyone who has a fibromyoma or to anyone who has been irradiated for menopausal bleeding.

**Avascular Necrosis of Fracture Fragments.**—Compere shows that a large fragment in a comminuted fracture of the femur, tibia, humerus or one of the bones of the forearm may be so detached from surrounding soft tissue that nutrient, metaphysial and periosteal blood vessels supplying the fragment are separated from it. In a diagrammatic illustration of sources of blood supply to the more important long bones the author shows that most long bones have only one principal nutrient artery. Approximately one half of the thickness of the outer cortex of the bone is nourished by the very small periosteal communicating vessels. A segment which is completely detached from the end fragments will retain little blood supply unless the nutrient artery is intact and supplies this fragment. The author presents case reports to demonstrate the typical course of a segmental fracture of a major long bone. He feels that the larger the separate fragment in a segmental fracture in a long bone, the poorer the prognosis from the standpoint of viability of that fragment. In the event that a fragment is partially devitalized and does not retain enough intact blood vessels to maintain a reasonable exchange of arterial and venous blood, some of the bone cells will die. If most of these cells die, the fragment will become necrotic, although massive sequestration does not occur. Union may then be delayed for many months. With good fixation, however, healing of the fracture will take place before the large fragment has undergone complete replacement by creeping substitution. If a principal nutrient artery remains uninjured and supplies the large segmental fragment, aseptic necrosis may not occur, and the prognosis for undelayed healing of the fracture is good.

**The Iliotibial Band Producing Deformity in Poliomyelitis.**—Irwin believes that the iliotibial band with its allied structures is probably the greatest deforming factor in involvement of the lower part of the trunk and lower extremities following infantile paralysis. The iliotibial band is the thickened portion of the fascia lata along its lateral aspect. Involvement of the muscles attached to this band is responsible for the increased tension under which it is placed during the acute and early convalescent stages of poliomyelitis. If the increased tension in the iliotibial band during the acute or early convalescent stage is not released by adequate conservative care, this tension becomes a progressive contracture. Treatment in the acute stage should be continued until the joints of the hip and the knee can be passively carried through their full range of motion in all directions without force and without pain or discomfort. When this has been accomplished, deformities due to contracture will not occur. A contracture of the iliotibial band on one side may contribute to the development of the following deformities: flexion and abduction contractures of the hip; contracture of the thigh in external rotation; genu valgum; knee flexion deformity and external torsion of the tibia; varus deformity of the foot; pelvic obliquity and exaggerated lumbar lordosis. A contracture, or shortening, of the iliotibial band cannot be corrected with conservative stretching and manipulation; neither can it be overcome by the application of plaster casts. Surgical intervention is indicated. A fasciotomy of the Ober type for the hip and a Yount fasciotomy for the iliotibial band and lateral intermuscular septum are the operative procedures of choice. The author briefly describes Ober's fasciotomy and gives his concept of a Yount fasciotomy. He also describes the postoperative correction in cases of unilateral deformity. The surgeon who attempts to correct and to fuse a curve in the lumbar part of the spine, when the pelvis is part of the curve, invites disaster if, before doing the fusion, he does not release all contractures below the crest of the ilium which contribute to the deformity.

**Hypercalcemic Syndrome Associated with Hormone Therapy.**—Herrmann and his co-workers found that in the course of treatment with testosterone propionate and diethylstilbestrol 4 patients, 3 with osteolytic lesions secondary to mammary carcinoma and 1 with an osteolytic lesion of a reticulum cell sarcoma, had toxic reactions associated with hypercalcemia and signs and symptoms of renal insufficiency. Several of these toxic episodes were corrected by the cessation of hormonal therapy and the institution of parenteral therapy consisting of infusions of isotonic sodium chloride and dextrose, and sodium citrate. Subsequent toxic episodes following reinstitution of hormonal therapy proved irreversible and had a lethal outcome. All the patients sustained renal damage with nephrocalcinosis. The hypercalcemic syndrome appears to occur relatively infrequently in patients with osteolytic lesions treated with these hormonal agents. Its incidence might be reduced by careful screening of the patients. Several criteria for the selection of appropriate cases are suggested.

**Vitamin E in the Menopause.**—Finkler resorted to vitamin E therapy in 66 selected patients who complained of the characteristic vasomotor symptoms of the menopause. In 59 of these women it seemed advisable to avoid estrogenic therapy. In the other patients there was no contraindication to the use of estrogens, and vitamin E was administered either before or after estrogenic therapy for the purpose of comparing the results. The daily dose of vitamin E ranged from 20 to 100 mg.; the average was 30 mg. in divided doses. Therapy was continued for periods ranging from ten days to seven months, with an average duration of thirty-one days. Good to excellent results were obtained in 31 women, and fair results in 16. In 19 patients the treatment was ineffectual. Discontinuance of the vitamin E preparation was attended by prompt recurrence of symptoms, with relief resulting again on reinstitution of the medication. Substitution of placebo medication for the vitamin E preparation in 17 patients caused a recurrence of symptoms. No changes in the breasts, uterus or vaginal epithelium were noted during vitamin E therapy. Side effects were negligible and there were no contraindications to its use.

**Use of Blood Donors with Positive Serologic Reactions.**—Ravitch and his associates say that before 1939, 12 cases of transfusion syphilis were observed at Johns Hopkins Hospital. Since the establishment of the blood bank in that year, no such cases have been recognized. With serologically tested blood available at all times, transfusion syphilis is no longer caused by the use of untested blood in conditions of dire emergency. However, among the large number of donors bled there must have been some who had lesions of primary syphilis. It is accepted that some 30 per cent of such persons are seronegative. It is from just such donors that one fourth of the cases of transfusion syphilis originated in the past. The authors believe that refrigerator storage is the factor responsible for the fact that such cases have not been observed since 1939. They present studies that were carried out to verify this. Patients given transfusions of plasma from donors with a positive serologic reaction for syphilis will acquire a positive serologic reaction for syphilis. The initial titer of the acquired serologic reaction for syphilis represents the dilution in the recipient's blood volume of the reagin contained in the injected plasma. In all of 16 recipients the acquired positive serologic reaction for syphilis had reverted to negative by the twentieth day or before. The authors are of the opinion that blood of donors with syphilis should be acceptable for use in any blood bank with a plasma program, provided the material has been frozen, dried from the frozen state or stored at least four days in the refrigerator.

**Insulin Dystrophy.**—Yohalem and Pollack say that shortly after the introduction of insulin reports began to appear concerning local atrophy and, less commonly, hypertrophy. The reported incidences varied considerably. The authors investigated this problem on a representative group of patients observed at the Diabetic Clinic of the Mount Sinai Hospital. Two hundred and fifty-five adult patients with diabetes of sufficient severity to require insulin were selected at random. Superficial indurations were considered to represent nonspecific reactions such as are seen in morphine addicts. The positive findings include atrophy of varying degree, hypertrophy, deep indurations of the subcutaneous tissues and combinations of all three. By these rigid criteria 43 per cent of the patients were found to have lesions. Pure atrophy, or atrophy and induration, was found in 33 per cent. Deep induration alone was found in 4 per cent. Hypertrophy was found in only 3 per cent of this series. It was found that the patients with the most severe atrophy were women; their diabetes was mild and easily managed, and they had been taking insulin a relatively short time, none more than six years. A higher percentage of the patients with skin changes were using an oblique technic than those without skin changes. There seemed to be support both in the history of the individual patients and in the decreasing incidence in patients with diabetes of longer duration for the theory that regardless of whether or not the injections were continued in the same site, the lesions, at least in some cases, reconstituted themselves. The cause of the changes seems to be a local quality of the fat tissue.

**Penicillin in Oral Surgery.**—Northrop recommends light frosting of a wound or cavity, especially after the removal of an impacted tooth, with penicillin powder of the calcium salt (5,000 units to 1 Gm. of equal parts sulfanilamide and sulfathiazole) as a routine procedure. In addition to this use of powdered penicillin and sulfonamide compounds, any site may be insufflated in the manner recommended, not as a routine method, but when excessive trauma is necessary and where infection or complications are more apt to occur. Since the great majority of dental and oral infections are caused by organisms which are sensitive to penicillin, it seems reasonable to expect considerable benefit from the use of this drug. Penicillin in adequate doses should be administered prophylactically to all patients with endocarditis when traumatic dental procedures must be performed, but also when inflammatory processes exist whereby bacteria may invade the blood stream. When surgical procedures are necessary, 2 cc. of procaine penicillin in oil, or 600,000 units, should be administered in the deltoid or gluteal muscle twenty-four hours prior to surgery. The same preparation and dose should be repeated at the time of operation. This product should be administered again in the same dose twenty-four hours after surgical procedure. Daily injections should be continued, the same dose being used, if oral sepsis is severe and healing does not readily take place, until the danger of bacteremia is over. Injecting 600,000 units of penicillin in a single daily dose over as long a period as necessary would seem indicated in the prophylactic care of any patient with endocarditis when infectious process exists in the oral cavity, in treatment of root canal and gingiva or whenever there is a possibility of bacteremia.

**Sympathetic Nervous System in Acute Poliomyelitis.**—Smith and his co-workers present clinical evidence of the involvement of the sympathetic nervous system in acute poliomyelitis which may manifest itself in the cervical region by Horner's syndrome, in the thoracic region by spasm of the pulmonary blood vessels with dilatation and irregularity of the right side of the heart, in the gastric region by pylorospasm, in the intestinal region by constipation or diarrhea, in the rectal region by intestinal obstruction, in the bladder region by retention or incontinence of urine and in the skin by angioparesis or spasm. The blood vessels in the extremity with chronic poliomyelitis have a response similar to the angiospasm of Raynaud's disease or the cramplike pain in intermittent peripheral arterial claudication. Evidence that the blood vessels were in spasm was found in the 12 patients tested with the oscillometer. The excursions were far below normal. Angiospasm was present in the encephalitic, the paralytic and the nonparalytic extremity of acute poliomyelitis. Pathologic changes were found in the lateral horn and in the sympathetic ganglions; these changes substantiate the clinical aspects. The authors found that short wave diathermy with the rhythmic constrictor dilated the blood vessels and increased the blood supply to the extremity. The muscles relaxed and the pain diminished or subsided, only to return when the blood vessels contracted. The authors feel, however, that neither short wave diathermy nor hot packs are the solution for the relief of the muscle spasm and pain in acute poliomyelitis, since these methods do not produce sustained vasodilatation. The method of choice would be a drug.

**Colds in Children Attending Nursery School and in Those Who do Not.**—Subjects of this study by Diehl were 51 children between the ages of 23 months and 56 months. All children were above average in health status. Twenty-five were attending nursery school and 26 were not. The nursery school endeavored to keep sources of infection at a minimum. The number and severity of colds were checked from Jan. 28 to April 8, 1946. There was no statistically reliable difference in the number and severity of colds suffered by children who attended nursery school and those who did not.

**Toxicity of Carinamide.**—Davis and St. Goar report an 11 year old girl with subacute bacterial endocarditis who was successfully treated with penicillin and carinamide. Fever, increased capillary fragility and increased bleeding time occurred, presumably as a toxic effect of the carinamide. The toxicology of the carinamide reaction as manifested by this patient was not clear. Rutin apparently had some beneficial effect in preventing capillary fragility and increase in bleeding time. Beyer and his associates studied the pharmacology and toxicology of carinamide, but did not experience reactions such as illustrated by this patient. It is felt that until more clinical and laboratory experience has been obtained carinamide should be used with caution.

**Tuberculous Lupus.**—Gaumond treated 20 patients, 10 men and 10 women between the ages of 24 and 65, who had tuberculous lupus, with vitamin $D_2$ (calciferol). Fifteen milligrams—i.e., 600,000 units—of vitamin $D_2$ in alcoholic solution were given three times during the first week (1,800,000 units) and two times (1,200,000 units) during each of the three following weeks. Treatment was then continued for several months and even for more than a year with 600,000 units of vitamin $D_2$ once a week. A diet poor in fats and sodium chloride is recommended. It seems superfluous to add calcium to the vitamin $D_2$. Clinical and anatomic recovery resulted in 18 patients; a few small lupomas persisted in 2 patients. A temporary exacerbation occurred in nearly all cases at the beginning of the treatment, suggesting a direct biotropic reaction to the tuberculous process. The treatment was well tolerated. The mechanism of action of vitamin $D_2$ (calciferol) has not yet been determined, but disphosphorylation of the enzymes of which Koch's bacillus deprives its host might be considered.

**Amniotic Fluid and Meconium Embolism.**—Barron and his associates review reports on embolism caused by amniotic fluid and report 2 cases of their own. They believe that in labor the fluid and meconium probably are forced into the uterine sinuses by the strongly contracting organ. The fluid can also enter the maternal circulation during cesarean section. The particulate matter of the amniotic fluid—i. e., the meconium, vernix caseosa, lanugo hairs and epithelial squamae—is responsible for the embolic plugging of the pulmonary circulation.

**Reconstruction of Auricle with Diced Cartilage in Vitallium® Mold.**—Peer reported in 1943 a new method for reconstructing an auricle by inserting diced cartilage grafts in a perforated vitallium® ear mold and burying the mold with its cartilage filler beneath the patient's abdominal skin. Connective tissue and blood vessels grew through the openings in the mold and bound the separate cartilage segments together, thus forming a solid but somewhat elastic structure which was an exact duplication of the ear mold. This ear framework, formed with the patient's own rib cartilage and bound together by the patient's own connective tissue, was successfully transplanted beneath the skin in the ear region. The posterior surface of the cartilage and the raw scalp area were later covered with a split graft, and the distorted ear lobe sutured in the normal position. The auricle reconstructed in this manner was satisfactory in general outline and angle, but the finer detail present in the transplanted cartilage framework was obscured by the thickness of the overlying skin on the anterior surface of the auricle. There was also a tendency to form fibrous tissue beneath the skin, and the cartilaginous framework became somewhat flattened. Some of these complications have been overcome by a trimming operation. Since the first case the author has buried twenty-two additional vitallium® ear molds. One mold has been lost due to hematoma with later infection, and one diced cartilage framework became infected following transplantation in the ear region, resulting in partial loss of the cartilage. Seven ears have been completely reconstructed and 13 are in various stages of reconstruction.

**Metopon Hydrochloride.**—Eddy says that the Committee on Drug Addiction of the National Research Council recommended in 1946 that the new morphine derivative metopon hydrochloride be made available to physicians under the committee's supervision. Special licenses specified that the drug be put up in capsules only for oral administration; that it be sold on Narcotic Order to the attending physician only; that all orders be subject to acceptance by the committee; that the use of the drug be limited to terminal cancer cases, that the physician's statement accompanying an order must satisfactorily indicate fulfilment of that restriction and that the physician would be expected to report back to the committee on the use of the drug. The author, who acted for the committee, stresses that metopon hydrochloride is an effective oral analgesic for chronic pain, the use of which is accompanied by a high incidence of mental clarity and a low incidence of side reactions. Since cross tolerance between other narcotics and metopon seems to exist and since the latter does not fully satisfy an established dependence, the use of metopon is more satisfactory in patients who have little or no previous narcotic medication. Tolerance to metopon develops more slowly than tolerance to morphine.

**Anion Exchange Resin for Peptic Ulcer.**—Mark says that a synthetic resin, a polyethylene polyamine methylene substituted resin of diphenylol dimethyl methane and formaldehyde in basic form, was introduced by Spears and Pfeiffer and Kraemer for the medical management of peptic ulcers. Segal and associates reported that this resin was nontoxic in laboratory animals even when fed in large amounts over a long period of time. Marks reports his experiences with this resin in 30 unselected patients with peptic ulcer. The anion exchange resin (200 mesh) was available in two forms: capsules containing 0.25 Gm. each and cachets of 1 Gm. These were used interchangeably, the usual dose being 2 to 4 capsules or 1 cachet every two hours during waking time, with additional doses if required for pain at night. A generous bland diet was allowed and the use of other medication (sedatives, antispasmodics) restricted as much as possible. All the patients were ambulant. As symptoms subsided the dose was given every three hours and maintained from four to six weeks and longer when possible. Twenty-five of the 30 patients were favorably influenced by the resin either to the point of complete relief of symptoms or to a degree greater than that obtained with previously used alkalis. No undesirable side effects on bowel function, gastric secretion or acid-base balance were observed, and the author concludes that an anion exchange resin of this type is a useful adjunct in the symptomatic treatment of peptic ulcer.

**Effect of Phthalylsulfathiazole on Bleeding Time.**—Wright and his co-workers point out that sulfathalidine® (phthalylsulfathiazole), which effects a considerable reduction of the gram-negative bacteria of the bowel, also frequently causes an increase in bleeding. Other observers had noted a severe vitamin K deficiency with prolongation of clotting time in connection with the use of various sulfonamide compounds. This had been ascribed to the fact that bacteria are a natural source of vitamin K. The authors determined the bleeding time of patients before phthalylsulfathiazole therapy was started and after the patients had been given this drug. On the basis of their observations on 71 patients the authors arrive at the following conclusion: 1. When administered in therapeutic doses phthalylsulfathiazole increased the bleeding and clotting time. 2. The administration of vitamin K reduced this prolongation of the bleeding and clotting time in most instances. 3. All patients who received phthalylsulfathiazole preoperatively and postoperatively should, at the same time, receive vitamin K in order to prevent vitamin K deficiency and an increase in the bleeding and clotting time.

**Endometriosis: Its Surgical Significance.**—During 1,991 consecutive abdominal gynecologic operations Kelly and Schlademan found 179 histologically verified cases of endometriosis. The average age of these patients was 38 years. Endometriosis presents a gross appearance referred to as "puckered" areas, especially in the advanced stages. Early manifestations are characteristic in their "blueberry spot" form. Adhesions due to endometriosis are frequent and should not be confused with those caused by other pelvic inflammatory disease. The adhesions of the latter are generally broad and easily torn, while those of the former are tough and solid. Fixed retroversion of the uterus should always cause suspicion of endometriosis. Endometriosis has a low diagnostic index because of the variable history, symptoms and physical findings. The factor of increasing dysmenorrhea is frequent. With a complaint of painful periods it should be determined whether or not the dysmenorrhea has been present since menarche or has been acquired later. In most cases of endometriosis, the latter situation prevails. Thirty-two of the 179 patients had lesions of the rectosigmoid. Many of these complained of painful defecation, abdominal distention or flatulence immediately prior to or during the menstrual period. The peritoneal surface of the uterus, the wall of the uterus and the cul-de-sac were the most frequent sites of endometriosis. The extent and location of lesions and the age of the patient are decisive factors in the choice of the operation. Although most surgeons are in agreement that it is worth while to spend thirty minutes or more excising individual lesions rather than perform more radical procedures, the authors had to do radical procedures in 132 of their patients (hysterectomy in 130 and bilateral oophorectomy in 2). Thirty-eight of the women could be regarded as relatively fertile after surgical treatment. Eleven pregnancies have occurred in these 38 patients. *Although radical operations are often necessary, conservatism is advisable whenever possible.*

**Expectant Treatment of Placenta Previa.**—Gordon and Rosenthal point out that placenta previa is an important cause of maternal mortality and that the expectant treatment advocated by some is based on their experience and belief that hemorrhage, whether initial bleeding or subsequent and no matter how often repeated, will not cause death in the absence of vaginal examination or manipulation. They have studied 50 case reports of maternal deaths associated with placenta previa. In this series, antepartum hemorrhage caused death in but 1 patient, whose atypical symptoms point to an unusual degree of abruptio associated with placenta previa. Death was largely due to intrapartum and postpartum hemorrhage, operative trauma and sepsis. Blood replacement was for the most part inadequate. The dangers incident to mismanagement of delivery are far greater than the risk of prior expectant treatment. Vaginal or rectal examination should not be performed at home. Following admission to the hospital, after the first hemorrhage, the vagina and cervix should be inspected through a speculum which has been cautiously introduced. In the interest of the fetus, no other vaginal examination should be performed, notwithstanding recurrent bleeding, until one decides to terminate expectant treatment in about the thirty-eighth week of pregnancy, and then only when preparations for delivery, by cesarean section or otherwise, are complete with suitable blood replacement. Tamponade and dilating bags are obsolete, and version nearly so. Cesarean section will be indicated in most cases. Expectant treatment of placenta previa is safe under proper conditions. The patient should remain in the hospital during the period of expectancy.

**Treatment of Biliary Obstruction.**—Walter stresses that the degree of pathologic change in the gallbladder frequently is at variance with the severity of the symptoms, and hence the exact nature of the degree of pathologic change in the gallbladder cannot always be determined before operation. Although the cholecystogram is accurate in its positive disclosure of disease and stones, there may be stones which are nonopaque to roentgen rays. Many patients with cholecystitis and symptoms resulting therefrom have been given a diagnosis of angina pectoris. In the absence of a history of jaundice, stones in the common bile duct frequently are overlooked at operation. Noncalcareous benign obstruction of the biliary tract was found in about 10 per cent of a group of patients with recurring biliary colic and jaundice. Stricture of the common and hepatic bile ducts is usually characterized by a biliary fistula or a clinical picture not unlike that of stone in the common bile duct. Excellent results can be expected if the stricture is excised and the ends of the duct are united or the duct above the stricture is anastomosed to the intestine. Even in cases of recurring stricture the outlook is not hopeless, since an external biliary fistula can be established. Patients who give histories of persistent disabling postoperative biliary colic should be suspected of having a stone in the common duct until proved otherwise at exploration of the common duct. If a stone is not present and there is spasm of the sphincter of Oddi, anastomosis between the common duct and the duodenum usually suffices to relieve the attacks of colic. Carcinoma of bile ducts is rare and seldom lends itself to excision. In recent years resection of the head of the pancreas and the ampulla of Vater with the attached portion of duodenum has been performed successfully.

**Dicumarol® in Acute Coronary Thrombosis.**—In the 73 patients treated by Carmichael and Oetting the diagnosis of coronary thrombosis was established by clinical, electrocardiographic and laboratory methods. Thirty of these were given anticoagulant therapy, and the remaining 43 served as controls. Forty-three per cent of both groups required digitalis. In half of the control patients who received digitalis thrombo-embolic complications developed, while none of the dicumarolized patients receiving digitalis suffered vascular complications. This seems to indicate that digitalis is given with more safety to the patient under anticoagulant control. The administration of dicumarol® had no effect on the degree or duration of pain occurring with acute coronary thrombosis. In the control series there was an incidence of 27.9 per cent of thrombo-embolic phenomena, while among the patients receiving dicumarol® only 6.7 per cent had vascular complications. The average period of strict bed rest was reduced 4.8 days and the average period of hospitalization 7 days by the preventive action of dicumarol® on complicating thrombo-embolic phenomena. The mortality rate of the control group was 16.3 per cent, while that of the treated series was 13.3 per cent. The authors believe that if the incidence of cardiac enlargement, multiple attacks of coronary thrombosis and shock had not been slightly greater in the dicumarolized group, the mortality rate for this group would have been lower. Serious hemorrhage with dicumarol® therapy is uncommon. The authors feel that in patients otherwise suited for anticoagulant therapy the use of dicumarol® should be part of the active therapeutic regimen.

**Optic Neuritis and Sinusitis.**—Northington and Rouen present the case of a woman who was hospitalized with a complaint of pain in the left eye, especially on movement of the eye, pain in the region of the maxillary sinuses and blurring of vision in the left eye. The present illness began ten days before admission when she awakened with obstruction to nasal breathing with profuse drainage. The pain and blurring of vision developed on the third day after onset of illness. Examination disclosed a purulent infection of all the nasal accessory sinuses except the frontal sinuses, but the posterior ethmoids and sphenoids were those chiefly involved. Treatment consisted of penicillin, 30,000 units every three hours; sulfadiazine, 1 Gm. every three hours; thiamine hydrochloride, 25 mg. daily, and irrigations of the sphenoid and maxillary sinuses. The symptoms subsided promptly. On the eleventh day of treatment the sinuses were clear, visual acuity and visual fields were normal, but the slight elevation of the nerve head persisted and did not subside until about three weeks later. The authors feel that in patients with optic neuritis an examination of the nasal accessory sinuses should be included in the search to determine the cause, and when a purulent sinusitis is present, suitable therapeutic measures should be employed.

**Experiments on Therapy of Schistosomiasis.**—Kikuth and Gönnert say that the aim of their chemotherapeutic work was discovery of a compound which could be given by mouth and would be suitable for mass treatment. This aim seems to have been accomplished in the discovery of the miracils,® which are compounds belonging to the xanthone and thioxanthone class. These compounds have differing activities in mouse and monkey schistosomiasis. In mice, miracil B® is highly effective. In monkeys, miracil D® is the best and produces cure in one dose of 20 mg. per kilogram or two doses of 10 mg. per kilogram, or sometimes even with two doses of 5 mg. per kilogram. Since the parasite is the same in mouse and monkey, this difference in activity can be due only to the physiologic differences in the two species of animals. Since monkeys physiologically resemble man in many ways, it is believed that miracil D® will be the best preparation for human schistosomiasis. In animal experiments the drug has a practical advantage over present day preparations used for schistosomiasis in that it can be given by mouth. If miracil D,® which is proposed for clinical trial in view of the animal results, should prove insufficiently active it would be desirable to test the related compounds for their value in human therapy. In that case the authors would first recommend miracil B® or the corresponding compound in the thioxanthone series.

Nephrocalcinosis Infantum with Hyperchloremic Acidosis. H. J. Boutourline-Young.—p. 181.

**Oral Reaction to Penicillin.**—Cross is concerned with reactions to penicillin when used locally in the mouth. His investigations were made on a total of 59 persons, of whom 11 were observed personally. The two common conditions are discoloration of the tongue and stomatitis. Discoloration of the tongue occurs in at least 30 per cent of patients taking penicillin continuously for oral conditions. It is often unnoticed by the patient, and is not accompanied by discomfort. Discoloration begins two to four days after starting treatment and wears off in five to fourteen days. It may be yellowish brown, brownish green, greenish black or black. In a typical case of stomatitis due to penicillin the patient, who has been treated for three to five days with topical penicillin for some oral or pharyngeal condition, complains of soreness of the tongue and at times of the whole mouth and pharynx, with extreme discomfort on taking hot fluids, spiced foods and condiments, or on smoking, and occasionally ageusia and lack of salivation. The condition lasts six to ten days, but the loss of sense of taste may last some weeks. Neither nicotinamide deficiency nor the lozenge base is responsible for these oral reactions. Reactions do not occur until there has been a complete change in the character of the oral flora. This takes about forty-eight hours, and it seems reasonable to limit the use of penicillin for the treatment of oral infections to this length of time as a rule.

**Systemic Penicillin for Infected Hands.**—In an attempt to assess the value of systemic treatment with penicillin in patients with infections of the hand, 200,000 units in one daily dose was given as a routine to the outpatients attending the Infected Hands Clinic at the London Hospital from November 1946 to January 1948. The results in 380 so treated were compared with those not so treated. It was found that this routine did not greatly reduce the period of disability in uncomplicated cases, though there was some improvement. It resulted in the resolution of some early infections without incision and did not increase the disability in infections which had been treated conservatively and which were subsequently incised. It controlled systemic reaction and spread in cases of severe uncomplicated infection. It reduced the period of disability and probably the incidence of complicated cases. It greatly improved the functional end result in cases of arthritis and tenosynovitis. It resulted in a considerable saving of inpatient beds, admission of patients with infected hands being reduced by 52 per cent in spite of a much larger attendance at the outpatient clinic. It was found in terminal pulp infections that with increasing age there was a longer history of pain, a longer period of disability and a greater liability to osteomyelitis.

**Blood Changes in Peritonitis.**—Theron and Wilson point out that the cause of death in peritonitis and the mechanism of the circulatory collapse which precedes death are in many cases obscure. They studied 35 patients with severe peritonitis; nearly all were sufficiently ill at some time to give cause for anxiety, and 12 eventually died. Operation was done in 33 cases. Other measures included intravenous infusion of isotonic sodium chloride solution and 5 per cent dextrose solution combined with suction drainage of the stomach to prevent or treat ileus. Systemic penicillin therapy was used for pulmonary infections, and in some cases sulfonamide drugs were given as well. Reduction of blood volume, mainly of plasma volume, was fairly common in severe peritonitis. A reduction of 20 to 30 per cent of normal values was found before operation, in about half the cases of recovery and in a larger proportion of fatal cases. Under treatment with intravenous injections of nonprotein fluid the plasma volume in cases of recovery rose to normal or above normal, though in some instances the cell volume continued to fall for some days. In fatal cases the normal volumes were usually not regained, and sometimes a further fall took place before death. Changes in plasma volume were accompanied by parallel changes in total circulating plasma protein and a proportionately greater fall in circulating plasma albumin, the deficit of which persisted for two weeks or longer. The main causes of the volume reductions were ileus and exudation of plasma into the peritoneal cavity. Extravasation of blood into the bowel during ileus may have been partly responsible for the fall in cell volume. There was evidence that reduction of blood volume produced renal injury. Renal failure was sometimes an important cause of death. In some cases the blood volume was very low shortly before death, and the terminal collapse of the circulation could be attributed to oligemia alone. In others the blood volume was nearly normal, and some other factor, possibly bacterial intoxication, had destroyed the efficiency of the circulation.

Infant Respirator for Treatment of Asphyxia of Newborn. H. S. Patterson.—p. 64.

**Magnesium in Dysmenorrhea.**—Rawlings shows that the psychologic factor is important in dysmenorrhea and that the patient's mental outlook must be studied. The physician should try to find the patient's idea of why menstruation occurs, and if necessary correct or explain the rhythmic cycle in simple terms. In some instances of so-called spasmodic dysmenorrhea there may exist an incoordination of the rhythmic contractions of the corpus of the uterus and the relaxation of the cervical musculature. He discusses previous studies on magnesium in relation to the uterus and describes his results in a clinical trial of magnesium gluconate in doses of 20 grains (1.3 Gm.) for relief of spasmodic dysmenorrhea. In the treatment of premenstrual distress of 15 private patients, 13 were relieved, 2 failed to benefit and 5 were cured; of 4 factory patients, 4 were relieved, no follow-up being possible. In the treatment of menstrual distress of 12 private patients, 10 were relieved, 5 were cured—that is, no recurrence occurred—and 2 obtained partial relief; of 6 factory patients, 1 failed to benefit, 1 obtained doubtful benefit and the remainder were relieved but were not followed up.

*Cod Liver Oil in Treatment of Maxillary Sinusitis. T. Hünermann.—p. 447.

**Cod Liver Oil in Maxillary Sinusitis.**—Hünermann began to employ cod liver oil in the treatment of maxillary sinusitis ten years ago. The results obtained were so favorable that since then he has used this method routinely for diagnostic and therapeutic purposes. Following puncture of the maxillary sinus, he introduces, without previous irrigation, 2 cc. of cod liver oil. If there is no swelling of the mucosa and no secretion in the cavity, the cod liver oil remains in the cavity, which ordinarily has a capacity of from 3 to 4 cc. If there is swelling or secretion, the cod liver oil will run out. It will displace any serous or purulent secretion that may be present in the sinus. If only the oil without an admixture of secretion runs out, a polypous proliferation of the mucosal lining exists. Thus, instillation of cod liver oil has a diagnostic value in that it reveals contraction of the lumen and presence and nature of the secretion. The chief purpose of instillation of cod liver oil is therapeutic. It replaces the secretion and exerts a favorable effect on the inflammation. In many instances not only was the suppurating maxillary sinusitis favorably influenced by the cod liver oil, but accompanying bronchitis and otitis media were also cured.

*Experimental Study on Placental Transmission of Penicillin by Comparative Titration of This Antibiotic in Maternal and Fetal Circulations. E. Grasset and E. Edlinger.—p. 510.
*Nuclear Aspects in Course of Various Phenomena of Microbic Lysis.* L. Quersin.—p. 522.

**Placental Transmission of Penicillin.**—Experiments performed by Grasset and Edlinger on 28 pregnant guinea pigs and 12 pregnant rabbits demonstrated placental transmission of penicillin as evidenced by comparative titration of this antibiotic in the circulation of mother and fetus. This transmission is relatively limited. It is influenced by the lapse of time following the injection of the antibiotic. No direct relationship was observed between the amount of penicillin injected into the mother and the level of the antibiotic in the fetal circulation. Under the experimental conditions concentration of penicillin in the fetal circulation may be maintained for three or four hours at a level definitely lower than that of the mother, but nevertheless of antibiotic therapeutic efficiency. The amniotic fluid contained only weak concentrations of penicillin which, toward the end of the period of gestation, were not appreciable by titration. The behavior of the placenta with regard to penicillin seems comparable to that observed with regard to vitamins.

Complicated, Open Rupture of Symphysis Caused by Spontaneous Delivery. W. Hinz.—p. 820.

**Sex Hormones for Pains of Endometriosis.**—Hoffmann points out that various sex hormones have been used to counteract the pain caused by endometriosis. In an effort to obtain insight into the mode of action of this treatment, the author made comparative therapeutic tests with different sex hormones on a woman, aged 40, who had a histologically verified endometriosis of the abdominal wall. She had pain in small nodules in the groins before and during the menstrual period. The pain first developed after an operation for correction of a retroflexion of the uterus. In a number of menstrual cycles several female and male hormone preparations were injected subcutaneously two or three fingerbreadths above the groin flexures. It was found that the effect of progesterone was somewhat better than that of testosterone, whereas estradiol had no effect whatever on the pain of endometriosis. The efficacy of the various sex hormones on the pain of endometriosis apparently depends on their progesterone content. He recommends progesterone for this purpose. He regards it as possible, but not definitely proved, that this effect is due to the spasmolytic effect of progesterone on smooth muscles.

*Granuloma of Bones. L. Tavernier.—p. 41.*

**Venous Graft in Arterial Thrombosis.**—Leriche and Kunlin report 8 patients with arterial thrombosis who were not benefited by vasodilator methods. Venous grafts, the size of which varied from 15 to 47 cm., were performed on these patients with the aid of heparin. Obliteration of the graft occurred on the third day in 1 patient with a graft of 47 cm., anastomosis having been performed between the iliac artery above and the popliteal below. All the other grafts remained permeable, some of them being followed up for five months, some for three months and the rest for several weeks. In all cases the posterior tibial and the pedal pulse was felt, oscillations were ample, the foot was warm, nutrition was good and ulcers healed. Patients who have not experienced sufficient improvement from sympathectomies may be benefited by this new method.

*Streptomycin in Treatment of Ozena and Purulent Rhinitis. J. H. Frenken.—p. 4223.

**Streptomycin in Ozena.**—Frenken points out that although the Klebsiella species that is regarded as the cause of ozena has been demonstrated to be sensitive to streptomycin, administration of streptomycin by the parenteral route (intramuscularly or intravenously) proved largely ineffective in ozena. The author reasoned that parenteral administration would probably not reach the ozena organisms in the crusts. He instilled a solution of streptomycin into the nose while the patient lay in the ventral decubitus position on a table, the head extending beyond the edge of the table. The head is turned to a side so that the nares are in a horizontal position. Solution is placed in one nostril and then, after it has spread in this nostril, the head is turned and the solution is instilled in the other nostril. Three cases are presented in which this treatment was effective. The solution used was prepared by suspending 1 Gm. (100,000 units) of streptomycin in 30 cc. of isotonic sodium chloride solution. From 2.5 to 3 cc. of this solution is instilled into each nostril three times a day on three consecutive days. Crust formation was reduced by this treatment and all other symptoms of ozena disappeared. Four months have elapsed without a recurrence. The author cites a case of purulent rhinitis in which the described treatment proved effective.

Vitamin Administration Before and After Operations. B. Snellman. —p. 2381.

**Clinical Symptoms in Disturbances in Water, Salt and Protein Balance.**—Fully developed disturbances of water, salt and protein balance, Aalkjaer says, can readily be diagnosed, but mixed types and slight disturbances present difficulties and call for various laboratory tests. Dehydration with simultaneous anemia manifests itself by hemoconcentration and small amount of concentrated urine. Acidosis, most frequent in disorders of the urinary tract, is often mistaken for uremia but can be diagnosed at once in the laboratory. Laboratory analyses are essential in the milder degrees of hypoproteinemia and alkalosis and in first stage shock. The laboratory can give the early diagnosis, the specific diagnosis and the quantitative diagnosis, needed for therapy, which is also to be early, specific and quantitative.

**Oxygen in Treatment of Disturbances in Water Balance.**—Ohlsson says that oxygen has proved to be especially valuable in the treatment of shock, not only in control of the hypoxia, but also because of a directly favorable effect on the circulation similar to that following administration of transfusion. As long as the state of shock continues there is no time limit in the treatment of a patient in shock with 100 per cent oxygen.

Role of Estrogenic Hormone in Pathogenesis of Carcinoma of Uterine Mucosa. L. Váczy.—p. 183.

**Mammary Cancer Following Use of Estrogen in Carcinoma of Prostate.**—Gardini reports a man in whom malignant degeneration of the breast resulted after treatment with estrogen had been continued for fourteen months (total of 350 mg.). The degeneration developed only in the left breast following the bilateral development of gynecomastia. Postmortem examination revealed an epithelial tumor in the prostate and bladder with numerous metastases in bones and lymph nodes. Some of the metastases had been present before the estrogen treatment was begun. The author mentions 9 similar cases in which carcinomatous degeneration of the breast developed in connection with estrogen treatment. This suggests the need for careful supervision of the patients during treatment with estrogenic hormones.

*Is It True That Silicosis is Not Progressive in the Absence of Tuberculosis? J. L. Nicod.—p. 51.

**Progressive Silicosis and Tuberculosis.**—Nicod does not agree with the conclusions of the conference on pneumonoconiosis held in London in April 1947, which asserted that pneumonoconiosis can be arrested spontaneously by the cessation of exposure to dust except for those cases in which silicosis is combined with tuberculosis. He performed necropsies on 150 miners who had been employed in the Swiss Alps and who had died from silicosis. Neither recent nor old tuberculous lesions could be demonstrated on microscopic examination of 35 to 40 per cent of these 150 men who had been working as miners only temporarily, in some cases not longer than one year, and who died from silicosis twelve to twenty-three years after having discontinued work in the silica dust environment. The postmortem examination revealed the progressive course of the silicosis in the pulmonary tissues and in the lymph nodes in the absence of any tuberculous process. In cases in which silicosis was combined with tuberculosis, the latter nearly always developed after the silicotic lesions in the lungs, and frequently it had an acute and terminal course. Tuberculosis is a late complication of the pneumonoconiosis in the great majority of silicotic patients.

*Mode of Action of Streptomycin on Tubercle Bacilli. C. A. Urquijo and J. A. Durrieu.—p. 726.

**Effect of Streptomycin on Tubercle Bacilli.**—Urquijo and Durrieu describe in detail the technic in testing sensibility or resistance of tubercle bacilli to streptomycin. They used a solid culture medium (Lowenstein-Saenz) on which the bacillary material was planted. The culture medium had been coagulated in the form of a beak, which gave an approximate culturing surface of 22 square centimeters. Twenty culture tubes were prepared for each sputum specimen. Immediately after planting, 4 tubes out of 20 were left as controls. The surface of the culture medium of the remaining 16 was covered with 5 drops of streptomycin solution at different concentrations, each of which contained a dose varying between 0.001 and 1 mg. of streptomycin. All tubes were then placed in an oblique position in the incubator at 37 C. The first reading of the tubes for colonies was made on the fifteenth day after planting, after which the readings were made every week up to the end of the thirty-eighth or forty-sixth day period of observation. At the end of this period it was found that streptomycin-sensitive strains of tubercle bacilli produced a large number of extensive bacterial colonies in the control tubes, delayed, small colonies in tubes with insufficient amount of streptomycin and no colonies at all in the tubes having sufficient amount of the drug. At the end of the period of observation all the tubes were placed in a vertical position and they were left out of the incubator at a maximal temperature of 33 C. for a week. An abundant number of extensive colonies had appeared within this week in 10 out of 28 tubes of three streptomycin-sensitive strains of tubercle bacilli which had had streptomycin solutions of different concentrations. Streptomycin was dissolved in the water of condensation (about 1 cc.) at the bottom of the tube. Near the streptomycin solution in the water of condensation there were no colonies. The authors believe that their findings confirm the opinion that streptomycin has bacteriostatic rather than bactericidal effects on tubercle bacilli.

*Pseudohemophilia. R. Etcheverri and O. France.—p. 29.

**Pseudohemophilia.**—Pseudohemophilia is a hereditary, congenital, capillary dysplasia, with no predilection for sex. It is due to lack of contractility of the capillaries. The clinical symptoms are similar to those of hemophilia but the time of coagulation of the blood is normal, whereas the bleeding time is prolonged. The subjects of this report are 9 members of a family in which the paternal grandfather, the father and 4 of 5 children had pseudohemophilia, whereas the paternal grandmother, the mother and 1 child were normal. The patients reported here began to bleed at the age of 3 years. Spontaneous, persistent and acute nosebleeds occurred at intervals of two or three months. The two young girls had, occasionally, profuse menstruation of one week's duration. There was neither anemia nor splenomegaly. The blood was normal. The coagulation time was normal. The bleeding time fluctuated between two and thirty minutes on different occasions in the same patient, it was normal during some of the determinations. The platelets were normal in number, but not in structure; they were round and granular. The blood group of the patients had no influence on the heredity of the disease, as the patients belonged to different groups. Blood of the only normal child was of the AB group. Myelograms from 1 of the patients showed medullary hyperplasia with predominance of megakaryocytes, and hyperregeneration of the erythroblasts. Administration of rutin in daily doses of 0.60 Gm. for three consecutive days had no effect on hemorrhages or on the prolonged bleeding time. The only available therapy is symptomatic; splenectomy is contraindicated, as it increases the danger of fatal postoperative hemorrhage.

Treatment of Epilepsy with Mesantoin-Phenobarbital Preparation (Hydantal). R. Stähli.—p. 11.

**Healing of Wounds After Local Treatment with Penicillin.**—Rauch performed experiments on himself producing wounds on both of his arms above the deltoid muscle. He irrigated the wounds on his right arm with a solution of 2,500 to 5,000 units of penicillin, and the wounds on the left arm with isotonic solution of sodium chloride. Closure of the wounds treated with penicillin occurred less rapidly than that of the control wounds. Granulation was more pronounced in control wounds which were infected artificially with staphylococci than in the wounds treated with penicillin. Microscopic examination of the wounds treated with penicillin and of the control wounds showed that the former presented a considerably larger exudation of fibrin and a reduced number of leukocytes as compared with the control wounds. The absence of bacterial toxins may be responsible for the reduced number of leukocytes, while the large exudation of fibrin may be explained by the effect of the penicillin on the capillaries. Intracutaneous tests on patients treated with penicillin and animal experiments in which a drop of penicillin was applied directly to the vessels showed that the effect of the penicillin on the vessels is almost exclusively toxic and allergic only in a very small degree. It is suggested that penicillin interferes with the effect of vitamins, preventing vascular permeability, and that this may be one of the components of its toxic effect on granulation. In the author's experiments, penicillin exerted a better effect on epithelization than diacetylaminoazotoluene, but the effect of sulfathiazole ointment on epithelization was superior to that of penicillin.

*Mass Roentgen Examinations for Tuberculosis During Childhood: Experiences and Results. R. Garsche.—p. 39.
International Combat of Epidemics, One of the Tasks of World Health Organizations. H. Reitzer.—p. 43.

**Mass Roentgen Examination for Tuberculosis During Childhood.**—According to Garsche miniature roentgen examination for the detection of tuberculosis is not as valuable in children as it is in adults. Particularly in younger children, adjustment of the proper position before the screen and awaiting the inspiratory phase requires considerable time. The author believes that the following points should be considered in the mass roentgenography of children: 1. Children less than 6 years old should not be subjected to such examinations. 2. In children up to 10 years, results of practical value require considerable expenditure of time and material. 3. In children over 10 years old, roentgenograms suitable for practical evaluation are obtainable, but even in these children considerably more time is required for examination than is the case in adults. 4. Mass roentgenography of children requires specially trained personnel, who are accustomed to handling children. 5. Evaluation of the roentgenograms should be carried out by a committee which includes a pediatrician with special training in roentgenoscopy. 6. When unselected groups of children are examined the results obtained are not as valuable as in adults and are not commensurate with the expenditure of energy, time and money. Therefore routine roentgenoscopy should be done only in children in whom it is deemed necessary, such as in those who might have been exposed.

*Clinical Experiences with Ultrasonic Energy. C. Wiethe.—p. 17.
Early and Late Complications After Strumectomies. R. Oppolzer.—p. 20.
Preoperative Roentgen Irradiation. O. Wichtl.—p. 24.

***Clinical Experiences with Ultrasonic Waves.***—*According* to Wiethe ultrasonic waves are mechanical waves of high frequency. The mode of action of this form of energy is different from that of other physical methods used heretofore. Ultrasonic or suprasonic waves have frequencies exceeding 16,000 per second. Increasing frequency of oscillations and the involved shortening of the wavelengths are accompanied by a bunching of waves, and this in turn results in greater density, which makes this form of energy suitable for diagnostic as well as therapeutic purposes. Frequencies of 500,000 to 2,000,000 oscillations per second are the ones used for therapeutic purposes. The production of mechanical oscillations of such high frequencies is generally effected by two methods, magnetostriction and the piezoelectrical effect. The latter method is the one usually employed in present day ultrasonic wave apparatus. At his clinic, which specializes in otologic disorders, suprasonic waves were employed in otosclerosis, Ménière's disease and in other auditory disturbances. In otosclerosis perception for ordinary speech, as well as for whispering, was greatly improved and the field of hearing was extended to as much as two octaves, chiefly in the lower range. In patients with Ménière's disease pressure in the head, ear noises and vertigo subsided or were improved and hearing was better. Suprasonic waves were tried also on patients with carcinomatous metastases in the region of the neck and later also in primary carcinomas of the parotid gland. Regressive changes were noticeable in the neoplasms.

# Book Notices

**Recent Advances in Cardiology.** By Terence East, M.D., D.M., F.R.C.P., Physician-in-charge of Cardiological Department, King's College Hospital, London, and Curtis Bain, M.C., D.M., F.R.C.P., Physician-in-charge of Cardiographic Department, Royal Bath Hospital, Harrogate. Fourth edition. Cloth. Price, $6.25. Pp. 454, with 125 illustrations. The Blakiston Company, Division of Doubleday Company, Inc., 1012 Walnut St., Philadelphia 5; Toronto, Canada, 1948.

The first edition of this volume appeared in 1929, and the third in 1936. The expanding knowledge of the past ten years required an entire rewriting of the book for this fourth edition. It is, however, more than a review of literature, since the subjects covered are summarized and evaluated in the simple, clear language characteristic of these commentators. The authors remark that "much is in the melting pot" and "what is new and what is an advance is often conjectural." The rapid developments in cardiology make it impossible for books of this sort to be completely up to the moment in their coverage, but the results in this volume justify the difficult screening demanded.

The subjects are first considered etiologically, then under the headings of disorders of function, heart failure, treatment, vascular diseases, peripheral circulatory failure and "new theories about cardiograms."

The discussion of congenital heart disease of necessity lacks reference to Taussig's book, which was in press during the preparation of this volume, and some of the newer knowledge brought out by intracardiac catheterization also was not available.

There is less reliance on, or perhaps experience with, penicillin than would be noted in an American book; for example, in the control of hemolytic streptococcic infections in the pattern of rheumatic fever. The role of penicillin in the treatment of syphilis is considered as still "to be ascertained."

The chapter on hypertension will be found useful, as 162 references are reviewed.

In the prevention of pulmonary embolus it is stated that "If it is certain that there is thrombosis in the leg, ligature of the femoral vein on that side is becoming widely adopted in the United States." The reviewer believes that most authors recommending ligation advise that it be bilateral if there is a suspicion of venous thrombosis on one side.

The discussion of the treatment of heart failure is excellent. Intravenous administration of mercurial diuretics seems to be preferred over intramuscular by these authors, but it may be that the relatively nonirritating mercurials are less available to them; similarly, heroin, which is advised for cough, is no longer legally obtainable in the United States.

The discussion of newer electrocardiographic theory helps to simplify an increasingly abstruse subject. Unipolar leads, the vector cardiogram, the ventricular gradient, and the effects of injury, ischemia, and myocardial infarct are succinctly covered.

In spite of an increasing interest in the recording of heart sounds and murmurs the literature of phonocardiography has been almost completely ignored.

This book will be found valuable by all who wish a compact review of the major advances in the cardiovascular field in the past ten years, as seen through the eyes of critical British clinicians. The book can be recommended for complete reading, or for reference, to medical students, general practitioners, and specialists.

**Pathology.** Edited by W. A. D. Anderson, M.A., M.D., F.A.C.P., Professor of Pathology and Bacteriology, Marquette University School of Medicine, Milwaukee. Cloth. Price, $15. Pp. 1453, with 1193 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1948.

In 1901, when Drs. Hektoen and Riesman published their "American Textbook of Pathology," they had the cooperation of seventeen authors to write on various sections in pathology. At that time it became clear to these authors that science, including medicine and pathology, has made such progress and has become enlarged to such an extent that it has become exceedingly difficult for one person to encompass the entire sphere. Hence, specialists with particular emphasis in a phase of investigation or teaching were called on to contribute chapters in their respective branches. In 1923, Aschoff published two volumes in pathologic anatomy with the assistance of sixteen authors. Here, again, the editor, a renowned pathologist, deemed it advisable to obtain various sections in pathology contributed by experts in their particular field. It is true that before and since the publication of textbooks by Hektoen and Riesman, and Aschoff, textbooks in pathology appeared by individual authors and each book approached the problem of pathology from different points of view. Some authors have stressed anatomic pathology, including histopathologic changes; others have correlated pathologic findings with physiologic and clinical alterations. Some have stressed nutritional, functional and chemical alterations. All have served a definite objective. These textbooks were used either as student textbooks in pathology or as reference books by the more advanced students in the field of pathology.

Anderson's book in pathology is unique in that it transcends all levels of purposes in the field of pathology. It can be used as a textbook for students under the guidance of understanding teachers in pathology. The graduate student as well as the trained pathologist will find valuable information on numerous subjects in Anderson's "Pathology." Here, again, Anderson has obtained the experiences of thirty-one specialists in pathology. Each has contributed one or more chapters pertaining to his particular forte in pathology. This lends strength to the meaning of the book, for we find the discussion of a subject by a seasoned pathologist in that phase of pathologic anatomy which he is most familiar with. Aside from the usual subjects discussed in the textbooks of pathology, there is a more elaborate and valuable dissertation on subjects like physical agents on the causation of injury and disease, chemical injury, effects of radiation, the skin, the bones and joints, subjects which are discussed here in more detail than is usually found in most textbooks on pathology.

Anderson's book covers 1,453 pages. It is rather voluminous as to size. The reviewer at the beginning was somewhat disturbed about the large and small type appearing on practically every page, but this slight disturbance was compensated for by the fact that the authors of this volume had a considerable amount to contribute in the discussion of their subjects. The assumption is that both the editor and the publisher elected to use smaller type in order to save space in the book. But this is a relatively minor comment. The reproductions are very good and illustrate the essential problems in pathology. An added feature of this book is that the bibliography at the end of each chapter covers the most important contributions to the subject. This should be an added advantage to the student in pathology in that his attention is directed to the important literature on the subject, if he desires a more detailed discussion.

Anderson's book is recommended to all students in pathology, in that it covers a variety of subjects with information that is important to every physician and transcends all levels from the student to the experienced physician and teacher. Anderson's "Pathology" should be in the possession of every physician interested in the scientific study of disease processes.

**Handbuch der Therapie: Therapie des praktischen Arztes in Einzeldarstellungen.** Herausgegeben von Prof. Dr. T. Gordonoff, Bern. Lieferung III: Ernährungslehre und Diätetik. Bearbeitet von Dr. Michel J. Demole, Dozent für Diätetik an der Universität Genf, Prof. Dr. A. Fleisch, Director des Physiologischen Instituts der Universität Lausanne, und Dr. Cl. Petitpierre, Dozent für Physiologie an der Universität Lausanne. Paper. Price, 24.80 Swiss francs. Pp. 382. Hans Huber, Marktgasse 9, Bern 16; distributed by Grune & Stratton, Inc., 381 4th Ave., New York 16, 1948.

This is essentially a handbook of practical dietetics for the physician. In contrast with the current custom in writing similar books in the United States, the emphasis is on calories, digestibility and the relations between proteins, fats and carbohydrates, rather than on individual vitamins and amino acids and specific deficiencies. Different categories of patients are taken up systematically rather than the reverse emphasis on the systematic discussion of the nutrients. This makes for a less elegant (or should one say less pretentious?) treatment; it is not necessarily less useful on this account. In any case this is a clinical work, simply and clearly written and yet based on sound knowledge and experience. It may be suspected that this is precisely what the practicing physician really wants and needs in this country, instead of more handbooks and monographs in which the trappings of scholarship invite the researcher rather than the clinician who only wants the best current advice on the dietetic management of his patients. For the research worker, the greatest interest in this book is the exposition of what, in the way of dietary treatment, is actually being recommended for use in Switzerland and the arguments for these recommendations. These turn out to be not dissimilar to good practice in the United States. In both cases it is obvious that the rationale and real scientific evidence for dietetic management are less definite than are the decisions which necessarily are made in every day practice. In both cases it is obvious that, at present, decisions about dietary management must often be made without satisfactory scientific evidence. The task of the physician is to begin his treatment on the best facts and reasoning available, but to be prepared to modify the program according to the progress of the case. The present book gives a good basis for this approach.

**Happy Days with Our Friends.** By Elizabeth Montgomery and W. W. Bauer, M.D. [Including Teaching Suggestions.] Guidebook for the Health and Personal Development, Primer. Cloth. Price, 96 cents. Pp. 80; 95, with illustrations. Scott, Foresman and Company, 433 E. Erie St., Chicago 11, 1948.

This book is designed for the 6 year old and is the introductory volume of a new health series. The teachers' edition offers aids for the instructor in presenting the materials including a statement of aims and purposes, a section on the characteristics and needs of 6 year olds and suggestions for making the most of the health information provided. Lesson plans outline ways in which the twenty stories can be introduced and suggest methods of developing discussion and of furnishing concurrent health education experiences of a functional type. The importance of home-school cooperation and the implications for close parent-teacher contact in solving child health problems are also emphasized.

The stories themselves are closely keyed to the interests of 6 year olds, and the fictional child characters will soon become old familiar friends of the reader. Much of the material is presented through attractive colored pictures which aid in avoiding the problem of too great reading difficulty often encountered in beginning health textbooks. In this connection only a few new words are introduced in each story with the reading level carefully checked so as to make the book one that the whole class can enjoy together. Additional sources of information for the teacher are listed in brief selective bibliographies.

The nature of the text makes it useful both as a supplementary reader and as a means of health instruction. However, if the health education values are to be realized, the health implications will need to be stressed. Physicians need have no hesitancy in endorsing the use of this book in schools where it is to be employed as intended.

**You.** By Helen Shacter, Ph.D., and W. W. Bauer, M.D. [Including Guidebook Material for Teachers.] Guidebook for the Health and Personal Development, Book 5. Cloth. Price, $1.48. Pp. 127; 288, with illustrations. Scott, Foresman and Company, 433 E. Erie St., Chicago 11, 1948.

This is the fifth grade book in a new health series containing a specially prepared section designed to aid the teacher in using the volume. Introductory material outlines aims and describes the needs and characteristics of preadolescents. Methods through which the teacher can contribute to improving the mental and emotional as well as the physical environment in the schoolroom are pointed out. Lesson plans include suggestions for introducing each unit for reading and discussion, and for promoting cooperation between parents and teachers in dealing with the health problems of children. A useful list of books, pamphlets, magazines and films for children, teachers and parents is included.

The material for pupils is not confined to physical health but treats mental health and social growth as an inseparable part of total development. Safety is woven into the content as an integral part of the program of health instruction. Stories of boys and girls who are faced with realistic problems found in daily living will be reflected in the actual experiences of the children who use the books. Excellent illustrations including colored pictures, drawings and cartoons will be an additional positive factor in motivation.

Prepared by a physician-educator team the book is up to date and reliable from both the medical and the pedagogic point of view. School medical advisers and other physicians who may be called on to advise about the use of health textbooks in schools can safely recommend this book.

**The Pharmacologic Principles of Medical Practice: A Textbook on Pharmacology and Therapeutics for Medical Students, Physicians, and the Members of the Professions Allied to Medicine.** By John C. Krantz, Jr., Professor of Pharmacology, School of Medicine, University of Maryland, and C. Jelleff Carr, Associate Professor of Pharmacology, School of Medicine, University of Maryland, Baltimore. Cloth. Price, $10. Pp. 980, with 94 illustrations. The Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1949.

In the preface to this volume is the statement "The central purpose of this treatise is to present the pharmacodynamic and pharmacotherapeutic actions of drugs as they are used in the treatment and cure of disease. The principal emphasis of drug action has been the clinical application, as the text is intended mainly for medical students and physicians who must use and evaluate drugs in the treatment of the sick." This purpose has been well fulfilled. The essential actions are described of the agents that have clinical value, and the volume is not encumbered with material of questionable value. The text is divided into nine parts, and these into chapters.

Part I: After a brief introduction, chapters are given to a presentation of the sources and nature of drugs; the various pharmaceutic preparations, pills, powders, the liquids, etc.; prescription writing; methods of administration and dosage, and, finally, a chapter on general pharmacologic principles and the response of cells to drugs.

Part II: The drugs and the newer antibiotics used in the treatment of malaria, syphilis, protozoan infections, helminthiasis, and bacterial infections are discussed. These include the sulfonamide compounds, penicillin, streptomycin and a few others of this group and are well presented. In this and the following sections are presentations of the history and nature of the diseases for which the discussed drugs are used and sketches of the men who discovered them—the latter of value to the medical student, particularly, for he gets little enough of this side of medicine.

Part III is on the response of the skin and mucous membranes to drugs. In part IV the response of the central nervous system to drugs is discussed. One chapter is on the physiology and pharmacology of the central nervous system, and ten chapters deal with the preparations used in therapy of this system—the alcohols, anesthetics, opium and its alkaloids and similar drugs and their addictions and problems; the barbiturates, diphenylhydantoin sodium and kindred drugs; hypnotics, analgesics and depressants. Part V is on the response of the autonomic system to drugs. The anatomy and physiology of these systems are presented clearly and at not too great length, as are the physiology and practical applications of the chemicals and drugs that act on them. The drugs of course include epinephrine and ephedrine, methacholine, the atropine, pilocarpine and physostigmine groups; there are chapters on nicotine, and a helpful discussion of the usage and abuse of tobacco.

The remaining parts present the action of drugs on the heart and circulation in health and disease; in hypertension, in the various diseases of the blood, on the reproductive system and, finally, on metabolism. Part VIII includes chapters on water balance, carbohydrate metabolism and insulin; the thyroid (in which one does miss Marine's work) and the metabolism of calcium and phosphorus in relation to rickets and spasmophilia. Drug poisoning and its treatment are discussed, with the presentation of the drug actions. Twelve pages of useful prescriptions in the metric system (fortunately) complete the text.

There is no special chapter on the use of drugs in pediatric practice, but occasionally useful references and comments are found. For a volume of nearly 1,000 pages this book is relatively small and "easy to handle." The type and paper are excellent; in brief, it is easy to read.

# Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

## HYPERHIDROSIS

*To the Editor:*—1. A young patient complains of excessive perspiration which discolors her clothing. The usual preparations do not bring relief. What treatment is recommended for this condition? 2. What is the best treatment for excessive oiliness of the scalp? The patient has dark brown hair.

M.D., West Virginia.

Answer.—First identify any causes for the hyperhidrosis, such as hyperthyroidism, tuberculosis, diabetes—any organic or functional disturbance of the nervous system, glands of internal secretion and the circulatory system. The application at frequent intervals of astringent preparations containing zinc sulfate, tannic acid or alum, 5 per cent in 70 per cent alcohol or in talcum, may give relief. For localized hyperhidrosis of the palms or the axillas, the application of 25 per cent aluminum chloride, used sparingly and not on irritated skin, is frequently beneficial. In extreme cases, those severe enough to constitute an economic or serious social handicap, benefit may be obtained from filtered roentgen rays carefully administered by an expert radiotherapist.

Excessive oiliness of the scalp usually can be controlled by adherence to a diet low in fats and stimulants, and the application of an astringent lotion for dark hair, such as: resorcinol, 4.0, salicylic acid, 4.0, mercury bichloride, 0.2, glycerine, 2.0 plus water and alcohol (95 per cent) to make 240.0.

## TREATMENT OF COMATOSE PATIENT

*To the Editor:*—How long can a human being be deprived of fluids or other intake before suffering irreparable damage? How long can life be maintained under these circumstances? How soon after a cerebral accident can a comatose patient with severe hypertension and cardiac damage receive fluids?

M.D., Pennsylvania.

Answer.—Many variable factors affect the consequences of dehydration, so that it is impossible to answer the first question. The prior state of water balance, body and environmental temperature, extent of effort, level of basal metabolism, glycogen reserves, tissue and serum proteins and age all alter the reactions to dehydration. The comatose patient should not be permitted to become dehydrated; it is usually wise to begin slow intravenous or subcutaneous administration of fluids within twelve hours of the onset of coma. A twenty-four hour urine output of at least 500 cc., and preferably 1,200 cc., should be maintained by parenteral administration of fluids. Hypertension is not a contraindication. Azotemia (uremia) engendered by oliguria is a serious hazard. Cardiac support can and should be given by incorporating digitalis or digitoxin in the intravenous fluid, in doses as individually required. In the coincident presence of anemia, slow transfusion of whole blood may be indicated.

## TREATMENT OF FOOTBALL INJURIES

*To the Editor:*—I see a great many football injuries. Recently the trainer has been told that ice applied to injuries immediately was dangerous. What is your opinion?

J. R. Tucker, M.D., Williamsburg, Va.

Answer.—Authorities on the treatment of athletic injuries differ with regard to the wisdom of applying ice following certain types of injuries. Stevens and Phelps in their textbook on "The Control of Football Injuries" (New York, A. S. Barnes and Company, 1933) have said: "Compression with the application of an ice bag to constrict blood vessels is the first principle in the treatment of muscle bruises." But Thorndike in his textbook on "Athletic Injuries" (Philadelphia, Lea & Febiger, 1938) has said: "The most annoying skin inflammation that one encounters in caring for athletes is superficial phlebitis, which is the result of immediate packing of sprains and strains in ice. It represents a mild degree of frostbite and comes from careless application of ice to acute injuries. Owing to this complication we have forbidden the use of ice pack treatment altogether. In five years, 10 such cases have been encountered, mostly in thigh contusions. A better treatment is to place the injured part in an ice water whirlpool bath where the same effect is produced without the danger of air pockets and frostbite."

It is obvious that applications of cold are valuable in the early stages of treatment of recent contusions, and the procedure is a sound one provided the ice is not applied carelessly. Perhaps the variation in technic advised by Thorndike might be worthy of consideration. Certainly, with proper technic, such applications cannot be considered extremely dangerous, and, at worst, they can do nothing more than produce, as Thorndike says, "annoying skin inflammation."

## BLUE SCLERA IN NEGROES

*To the Editor:*—1. In the eyes of Negroes are the scleras whiter than in the white race? 2. Do blue scleras occur in Negroes and if so in what percentage?

Edmund P. Fowler, M.D., New York.

Answer.—Adler (Adler, F. H.: Gifford's Textbook of Ophthalmology, ed. 4, Philadelphia, W. B. Saunders Company, 1947, p. 251) stated: "The normal sclera is porcelain white with occasional pigment spots depending upon the general pigmentation of the individual. In the colored race, collections of brownish pigment are frequently found at the points of exit of the anterior ciliary arteries which may readily be mistaken for malignant melanoma."

Duke-Elder (Duke-Elder, W. S.: Text-Book of Ophthalmology, St. Louis, C. V. Mosby Company, 1933, p. 372) spoke of the "Negroid type (Negroes, Melanesians), with deep pigmentation in the superficial layers of the conjunctiva and round poorly-branching cells in the iris. Pergens (1898) noted a marked pericorneal pigment ring in the negroes of the Congo."

Definite cases of blue sclera in Negroes have not been reported, but many cases of blue sclera reported do not state the color or race (about one sixth do not state race). Harnett, W. L. (*Brit. J. Surg.* 22:269-273, 1934) reported "two cases of osteogenesis imperfecta with blue sclerotics in natives of India." Patient 1 was a Bengali boy, aged 10 years, and patient 2 was an Anglo-Indian (Eurasian) girl, aged 10. Jones Joseph (Mollities Ossium, *Tr. Am. M. A.* 20:365-432, 1869) reported a dark mulatto (case 10) aged 24 with fragilitas ossium; no mention was made of color of sclera. The patient's father, a light mulatto, had a niece, color not given, with fragilitas ossium.

## OLIGOSIALIA

*To the Editor:*—A woman 74 years of age has the chief complaint of dryness of the mouth. What saliva there is, is thick, tenacious and mucoid. In April 1947 she had purulent bilateral parotiditis. This cleared up with penicillin treatment but has left the patient as described. She has had a variety of treatments including gargles and sprays, pilocarpine capsules, potassium iodide, ammonium chloride and throat lozenges as well as the usual home remedies, chewing gum, sweet candies and lemon juice. Roentgenograms fail to reveal any calculi in the glands or in their ducts. Autogenous vaccine was suggested and tried without apparent benefit. Please suggest further treatment.

Edward T. Carey, M.D., Clinton, Iowa.

Answer.—The parotid infection, plus the age of the patient, would seem to be the cause of the xerostomia and oligosialia. These subjects have been discussed in Queries and Minor Notes on previous occasions. It would seem necessary to rule out only a few other causes—the use of medications containing belladonna, the presence of diabetes or chronic nephritis, any evidence of autonomic imbalance and the use of an astringent mouth wash.

The best drug to use as a test or treatment is neostigmine bromide (described by Pelner, *Am. J. Digest. Dis.* 9:417 [Dec.] 1942). When a half tablet (7.5 mg.) is given after each meal, a profuse thin salivary secretion occurs, and the oral symptoms subside. It is also suggested that the general health be improved as much as possible and that the oral condition (not mentioned) be treated if indicated, with local therapy and vitamin concentrates (notably B complex and nicotinamide).

## ERYTHROMELALGIA

*To the Editor:*—For a month I have been confined to bed because of a foot condition. Four doctors have been unable definitely to diagnose the condition. Its first appearance was similar to inflammatory rheumatism, but pain was absent except on pressure. Even the slightest pressure gave severe pain. Later the foot became a violent reddish purple; two of my associates thought that it resembled Buerger's disease and a third erythromelalgia. What is the latest information on erythromelalgia, its symptoms and treatment?

John C. Wilson, M.D., Wilcox, Ariz.

Answer:—The information which the inquirer furnishes is inadequate for an exact diagnosis. It is extremely improbable that a person would be confined to bed for a month because of erythromelalgia, which is a circulatory disturbance of the extremities characterized by intermittent episodes of burning distress in one or more digits or one or more extremities (usually the lower extremities) associated with increased warmth and reddish discoloration of the involved part. The skin of the involved parts in erythromelalgia has a "critical point"; that is, a temperature above which burning distress is present and below which burning distress disappears. This critical point has a variable value, but it is ordinarily in the neighborhood of 31 to 32 C. (87.8 to 89.6 F.). One of the characteristics of erythromelalgia is that any measure which will increase the temperature of the skin to a value greater than that of the critical point produces distress, and anything which decreases it to a value less than the critical point will cause the distress to disappear. Thus immersion in warm water (temperature greater than the critical point) will provoke the distress, and immersion of the part in cold water (temperature of a value less than the critical point) will cause the distress to disappear. Unless the inquirer can achieve relief of pain in the affected part by immersion of his foot in cold water, it is certain that he does not have erythromelalgia.

A diagnosis of thromboangiitis obliterans (Buerger's disease) must be based on the history and the findings of ischemia. The latter is characterized by absence of or diminution of the peripheral arterial pulsations, abnormal pallor of the skin of the affected part on elevation, prolonged venous filling time when the feet are moved from the elevated to the dependent position and coldness of the skin of the involved part when it is contrasted with that of the skin of symmetrically placed or companion parts. The possibilities of gout and reflex sympathetic dystrophy should be considered in the differential diagnosis along with some additional unusual conditions.

## FLUOROSCOPY IN OSTEOMYELITIS

**To the Editor:—Of what value is fluoroscopy in confirming the diagnosis of suspected osteomyelitis?**

**Harry J. Weber, M.D., Pakistan, Asia.**

Answer.—Roentgenologic diagnosis of early osteomyelitis is difficult. As compared with the clinical symptoms, the changes that are detectable roentgenologically are rather late in appearing. Roentgenograms of the best quality are needed to show the early manifestations of osteomyelitis. Fluoroscopy is not of value in diagnosing early osteomyelitis, as the changes occurring in that condition would be seen fluoroscopically only when extensive bone changes have occurred. It is probable that by fluoroscopy alone even advanced osteomyelitis could not be distinguished from other bone lesions. Therefore fluoroscopy has little to offer in the diagnosis of osteomyelitis.

## EPILEPSY IN CHILDREN

**To the Editor:—What are the best drugs to begin treatment of a 3 year old epileptic child who has never before had anticonvulsant therapy? This child has had grand and petit mal seizures since it was 10 weeks old. There is probably an etiologic factor of brain damage in this case. The baby was born of an Rh-negative mother and Rh-positive father and had a moderate degree of erythroblastic anemia and jaundice at birth. The infant was successfully treated with transfusions. The number of epileptic seizures of both types have been gradually increasing. Two or three grand mal and five or six petit mal episodes occur daily.**

**G. Alan Neufeld, M.D., Ottawa, Ill.**

Answer.—There are not any "best drugs" for the treatment of epilepsy. Assuming that a patient aged 3 has had epileptic attacks since the age of 10 weeks and that the seizures are on a basis of gross structural changes in the brain, treatment must be so designed as to provide anticonvulsive therapy for years and, perhaps, for the rest of the patient's life. It is also assumed that the nature of the lesion is such that an operation on the brain is not justified. Evidence was not presented of a focal nature of the seizures. Treatment under these conditions should consist of either a ketogenic diet, which has proved to be of considerable value when used in children, or the use of some drug to suppress both the number and the character of the seizures, in the hope of eliminating them without causing damage to the patient or giving rise to such untoward symptoms, resulting from their toxic action, as to make them untenable. Potassium bromide may cause irritation of the skin and therefore frequently cannot be taken continuously. The safest anticonvulsant is phenobarbital. It is not likely to cause untoward symptoms, remains effective over long periods of time and rarely causes gastric disturbance or skin eruption. Primarily useful in controlling attacks of grand mal, phenobarbital is less useful in seizures of the petit mal type. A combined formula, containing phenobarbital and potassium bromide, is often satisfactory. Phenobarbital, moreover, is sometimes combined to advantage with a ketogenic diet, and this is possibly the most advantageous treatment for patients with structural lesions of the brain.

Other drugs are now available, and each or a combination of two or more should be given consideration. They are as follows: diphenylhydantoin sodium (dilantin® sodium), methylphenylethyl hydantoin (mesantoin®), trimethadione (tridione®), or thyphenytoin® (5,5-phenylthienylhydantoin). They require careful evaluation. There is no rule to indicate the most efficient drug or which combination of drugs would be particularly advantageous. The matter must be worked out by a system of trial and error, and failure to do this results in many patients with epilepsy failing to achieve maximum results. It might take at least a year for a physician to find the best formula for this patient. The toxic symptoms resulting from their use may preclude use of any one of the four drugs mentioned in a long time program, even though the immediate results were satisfactory.

Thus the best form of treatment is not at once evident. A cautious but a persistent physician plus a cooperative family with a desire to find a satisfactory remedy should result in ultimate establishment of a successful treatment in a large percentage of patients with epilepsy in early childhood. Further information may be found in the following references:

## HORMONES IN BENIGN PROSTATIC HYPERTROPHY

**To the Editor:—Is there any evidence that therapy with female sex hormones ameliorates the condition of benign prostatic hypertrophy?**

**William A. Phillips, M.D., Quakertown, Pa.**

Answer.—The hormone treatment of benign prostatic hypertrophy is based on the established relationship between the prostate and endocrine glands in animals. This same relationship probably also exists in man, but many of its details remain unsolved. For this reason many conflicting observations have crept into medical literature regarding the hormonal treatment of benign prostatic enlargement. The substances most frequently recommended are estrogen, testosterone and inhibin. Favorable and unfavorable treatment results are recorded following their use. Daily small doses (1 to 2 mg. of diethylstilbestrol) of estrogens can temporarily relieve annoying vesical symptoms and produce a mild shrinkage of the prostatic adenoma. These improvements will cease when the drug has been discontinued. Hormones are not known that will permanently reduce the size of a benign enlarged prostate. The greatest usefulness of the estrogens now seems to be in advanced prostatic carcinoma.

## HISTAMINE DESENSITIZATION

**To the Editor:—What is the present status of histamine desensitization with special reference to allergic bronchial asthma in a child?**

**William A. Phillips, M.D., Quakertown, Pa.**

Answer.—Most of the experimental observations indicate that the repeated administration of histamine to animals does not increase the animal's tolerance to this chemical (Clark, W. G., and MacKay, E. M.: Effect of Histamine Pretreatment upon Some Physiological Changes Following Adrenalectomy, *Am. J. Physiol.* 126: 465, 1939. Wells, J. A.; Gray, J. S., and Dragstedt, C. A.: An Investigation of the Question of Histamine Tolerance, *J. Allergy* 13: 77, 1941). There is no good clinical evidence indicating that an increased tolerance in man can be achieved to histamine by its frequent injection. Indeed, clinicians who have been interested in the problem have observed that the tolerance dose of histamine after a series of injections is identical with the person's tolerance dose at the beginning of the treatment (Feinberg, S. M.: Histamine and Antihistaminic Agents: Their Experimental and Therapeutic Status, J. A. M. A. 132: 703, 1946). Possibly, some patients with such conditions as migraine or Ménière's syndrome are benefited by histamine injections. If this does happen, it must be due to a mechanism other than desensitization to histamine. Injections of histamine in the treatment of asthma, first advocated many years ago, has not found supporters in recent years.

## MALE SEX HORMONE IN DIABETES

**To the Editor:—Has male sex hormone been used with benefit in diabetes?**

**F. A. Mills, M.D., Rawlins, Wyo.**

Answer.—Impotency appearing after some years of diabetes is rarely benefited by administration of male sex hormones. In hemochromatosis with diabetes a small series of patients appears to have been helped somewhat as far as improvement in general strength is concerned. Testosterone has been used in a large series of children with benefit for growth but without beneficial influence so far as carbohydrate metabolism was concerned. A normal male should not take testosterone.

# THE LABORATORY IN DIAGNOSIS AND CONTROL OF DISEASE

FRANK W. KONZELMANN, M.D.
Atlantic City, N. J.

General practitioners form the most important of all the groups in American medicine. I hold this to be true for the following reasons: 1. There are more men in general practice than in any specialty. 2. They have closer contact and more frequent contacts with patients than any specialist. 3. They have more intimate first hand knowledge of the patient and his background and individual medical peculiarities than can be acquired in a few consultations. 4. They see the patient at the beginning of his illness. 5. They see the patient as a whole, not as just an eye, or an ear or a case of abdominal pain. 6. Their day often begins in the early morning hours with a problem in obstetrics and runs through psychiatry, metabolic disease, orthopedics, a little minor surgery, surgical diagnostic problems, pediatrics after school, geriatrics before dinner, cardiology after dinner and diseases of the respiratory tract in the evening office hours.

Longfellow was not thinking of the general practitioner when he wrote, ". . . the cares that infest the day shall fold their tents . . . and silently steal away."

Major surgery is the domain of the surgeon. New technics in minor surgery developed by the surgeon may be passed on to the men in general practice. In like manner, major pathologic technics such as bacteriologic studies, tissue diagnosis, some phases of chemical pathologic work and hematologic studies may be considered the domain of the pathologist. Minor pathologic technics developed in the laboratory by the pathologist should be included in general office practice.

## IMPORTANCE OF HISTORY AND PHYSICAL EXAMINATION

I place examination of the patient by use of the eyes, ears and hands above all else in the diagnosis. Without an adequate history and an expertly performed physical examination, all other diagnostic methods are apt to fail or to yield misleading information. Unless there is an intimate knowledge of the signs and symptoms neither the roentgenologic nor clinical laboratory studies can serve in their most dependable fashion. Haphazardly selected studies add needless expense and effort. In considering pain, one wants to know exactly where it is, how long the patient has had it, whether it radiates, and where; what its character is and whether it is relieved by or accentuated by pressure. To say that a patient has had abdominal pain for two days is not enough. A lengthy case study is not desirable. Sketches and marks on stamped outlines save many words, but questions and examination notes can be "to the point" and can be summed up in a provisional diagnosis or diagnoses. The laboratory can help in ruling out the incorrect and ruling in the correct diagnosis.

In cases of coma, the history may indicate the nature of the lesion. Doctors sometimes neglect this and order studies of blood urea, blood sugar and spinal fluid. One of these should certainly reveal the cause. Of these only the blood urea may appear abnormal, so that one takes for granted that the case is one of uremic coma. In the hospital ward someone performs, for good reason, a study of total nonprotein nitrogen and finds it elevated proportionately to the urea—exactly twice the urea level. The blood chloride level is found to be low—a state of hypochloremia. In retrospect the history reveals some one of the conditions leading to salt depletion—excessive sweating, diarrhea or prolonged vomiting. Much valuable time has been lost. Unnecessary laboratory work was done; essential studies were omitted, and the urea value was misleading. The patient is improved by intravenous injection of salt. If a history is not obtainable, further chemical studies should be made at once, which would distinguish one cause of increase of a blood constituent from another.

## OFFICE LABORATORY

Physicians cannot all have elaborate laboratory facilities at their command, but there are certain facilities which one may strive for, depending on the site of practice, whether it is a rural area, small town or city or a small or large hospital. Successful surgery of some types can be performed in an emergency by someone not a surgeon, with a kitchen knife, scissors and linen thread, with a few spoons for retractors. The physician who expects to meet such emergencies usually supplies himself with more adequate equipment.

A planned, properly supervised laboratory is desirable, but when there is none within 50 or 100 miles, the physician can have someone trained to do a urinalysis, ordinary blood cell count and determination of blood sugar, urea, nonprotein nitrogen, hematocrit, clotting time, bleeding time, prothrombin, total serum proteins, total serum bilirubin and urine urobilinogen, as described in the model laboratory in the exhibits. With ordinary care, sufficient accuracy may be accomplished for differential diagnosis in emergency cases. However, I do not approve of a physician's allowing a technician in his office independently to run a "clinical laboratory" for the benefit of neighboring physi-

Pathologist, Atlantic City Hospital, Atlantic City, N. J.

Read at the Interim Session of the American Medical Association, St. Louis, Dec. 1, 1948.

cians. Unsupervised, such work is entirely second rate and is invariably carried on not as a diagnostic aid, but as a business proposition. Office laboratory work should be undertaken only when a properly supervised laboratory is not available. The mail is available for transporting specimens to any laboratory equipped for more exacting studies by more intricate methods, when time is not so important a factor. Such facilities are available for almost every physician in this land, if he will but choose his studies wisely and collect his specimens correctly. The question of cost might arise in the case of indigent patients. I believe that, today at least indigence is a little overplayed. In New Jersey, and especially in my county, no examination is refused. Once or twice I have had occasion to ask a physician whether his practice is limited to indigents, or I might question the indigence of a patient living on "Rockefeller Boulevard."

### PURPOSES OF LABORATORY INVESTIGATION

There are indications for every laboratory investigation just as there are for any diagnostic or therapeutic procedure. I have already referred to the uselessness, danger and costliness of haphazard selection of laboratory tests. Three studies may be considered a part of every physical examination: (1) routine urinalysis plus the Harrison spot test for bile pigment, (2) a complete blood cell count and (3) a serologic test for syphilis. These three yield helpful information in such a wide variety of symptom complexes that such a plan of routine examination is time saving. Beyond this point the laboratory may be considered as serving three purposes: (1) to confirm a diagnosis which has been based on clinical signs and symptoms, (2) to reveal accurately the effect of treatment and (3) to reveal the nature of a disease when clinical signs and symptoms are obscure.

*Confirmation of Diagnosis.*—One may argue that laboratory confirmation is not necessary if clinical signs and symptoms are diagnostic. An example to the contrary is the case of a woman of 50 years who had severe anemia. She had had a breast removed because of carcinoma fifteen years previously. There was no evidence of recurrence externally or in a flat plain roentgenogram of the chest. A routine blood cell count revealed macrocytic anemia, and gastric analysis showed absence of hydrochloric acid. A diagnosis of pernicious anemia was made and liver therapy begun. There was not much response. Blood transfusion alone gave some relief. Sternal marrow aspiration showed a hypoplastic state, not a megaloblastic one. Had liver not been administered this observation might have had greater value, for in untreated pernicious anemia there are certain peculiar cells in the marrow called megaloblasts. The anemia in this case could have been classified as a refractory anemia, which is a rather meaningless classification. It seemed that this must be a case of anemia due to marrow destruction, even though roentgenologic study failed to reveal metastatic carcinoma. The whole skeleton was examined and a suspicious area in the femur located. At this point an aspirating needle was inserted. The material obtained showed cancer cells. The patient subsequently died, and at autopsy general spread of carcinoma throughout the bone marrow was revealed. Symptoms of mild or early diabetes with hyperglycemia and glycosuria may not indicate diabetes at all.

A sugar tolerance curve determined in the proper circumstances may uncover some other endocrine disturbance. Coronary artery disease may present symptoms referable to the liver and biliary tract. Properly selected laboratory tests might well locate the lesion in the liver area or establish the absence of pathologic change there. Ruptured gastric ulcer might be simulated by acute pancreatitis, and a serum amylase determination might well prove the existence of a pancreatic lesion.

I saw a patient with the diagnosis of appendicitis operated on without the benefit of a blood cell count. At operation an ulcerated appendix was discovered—a typhoid ulcer. The pronounced leukopenia later demonstrated might have suggested the true nature of the disease and an operation avoided. A more recent case is worthy of comment. A young girl of 16 presented symptoms of menstrual hemorrhages and intermenstrual bleeding. She was being treated for functional uterine bleeding. Delving into the history revealed that her spleen had been removed six or eight years previously because of thrombopenic purpura. Her physician argued that, since her spleen had been removed and she was apparently cured, her present state could not be a manifestation of this disease. Her thrombocyte count proved to be less than 50,000 in several examinations and her clot retraction time delayed. It is highly probable that she had an accessory spleen. If rest in bed at menstrual periods and blood transfusion do not prevent recurrence, exploration would be necessary. Results of laboratory studies would make one suspect that the patient was still suffering from essential thrombopenic purpura and that she still had splenic tissue somewhere.

*Laboratory Studies of Treatment Results.*—No one today attempts to treat diabetes without noting the effect of insulin on the urine and blood sugar. Usually transfusions for anemia are followed by blood cell counts. I have in mind a case of pernicious anemia properly diagnosed, in which the patient was given liver therapy. I urged that it would make a teaching case. There were frequent measurements of red cell size and hemoglobin content as well as total cell counts. The first week showed a good result. The red cell count and hemoglobin rose; the white cell count came up gradually. The size of red cells diminished; the hemoglobin content of the cells dropped slightly, and iron was added to the therapeutic regimen. After several weeks all these values reached normal except the leukocytes, which kept increasing. Then the level of hemoglobin and red cells began to fall, despite treatment. A bed sore had developed, and a cast had been applied to relieve the pressure. Naturally this area came under suspicion. The cast was opened over the area; it seemed clean, but later investigation showed that the infection had spread widely under the skin. This patient died of septicemia. Had the rising leukocyte count been considered more seriously and promptly, she might have lived.

The modern standards of red cell study are well demonstrated in the scientific exhibit. It is worthy of note that macrocytic anemias (large cell anemias) are usually caused by some disturbance of the antianemic factor and are most likely to be helped by liver therapy. The small cell anemias (microcytic anemias), especially if there is a low mean corpuscular hemoglobin (low hemoglobin content in each red cell), are most likely to respond to iron therapy alone. Some are due to systemic disease, such as diabetes and nephritis, and are helped little by iron unless the primary disease is also treated. Anemias in which red cells are of normal size (normocytic) are usually the result of acute hemorrhage or acute blood destruction.

It is frequently not possible to determine by clinical signs alone when some disease processes have subsided completely. In acute hepatitis, for example, jaundice may disappear, the patient may feel as if he has completely recovered, but a thymol turbidity test may reveal, by a positive result, that the process has not subsided. If that patient resumes normal activity, a relapse may occur more serious than the initial disease. The sulfobromophthalein sodium test is also helpful in this same respect. In recovery from acute nephritis, an Addis cell count or a blood urea clearance determination may well indicate the smoldering character of the infectious process. The sedimentation rate of red blood cells has similar significance in coronary disease.

From a public health point of view, a patient with typhoid should never be considered as recovered until the stool and urine are proved to be free of typhoid bacilli. A patient who has had diphtheria should not be discharged until throat smears fail to reveal diphtheria bacilli. A female child should never be admitted to a ward or rooms with other female children until a vaginal smear proves negative for gonococci.

Modern therapy requires control by laboratory studies. Treatment with sulfonamide drugs, gold salts, thiouracil or aminopyrine requires white blood cell counts and differential counts weekly or twice weekly. If the white cells drop to 2,500 per cubic millimeter, caution should be observed. If the white cells fall to 2,000 or 1,500 per cubic millimeter, therapy should be discontinued unless there is some good reason for its continuance. If a differential count is made, one is guided too by the percentage of neutrophils. A low percentage, even with a count of 2,500, is a danger signal during this sort of therapy. It is a wise physician who performs an occasional test for serum bilirubin while administering cinchophen and similar compounds. The first evidence of liver damage by these drugs will be evidenced by a rise in serum bilirubin levels.

*Laboratory Studies in Cases of Obscure Clinical Signs and Symptoms.*—Unexplained fevers call for special consideration. Our forefathers considered fever itself a disease—"lung fever," "childbed fever" and "swamp fever"—but today fever is recognized as only a symptom caused by invasion by some particular organism. For some there is a specific cure; for many, health departments must find the source of contagion so that epidemics may be averted. In all, an accurate diagnosis is necessary. The physician of yesterday was a keen observer of the manifestation of a particular fever—its curve on a chart and the character of its rash, but these are late manifestations. The examination of the blood for parasites and the blood culture for bacteria are helpful in the first week of disease. It must be remembered that a blood culture must not be discarded as negative until five, or preferably ten, days have elapsed. After five days a negative culture should be repeated. In the second week of an unexplained fever, agglutination tests must be considered. It is well to set up tests at one time for typhoid, paratyphoid A and B, Brucella abortus, antigens for the richettsial diseases (B. proteus OX k and OX 19) and B. tularensis. A negative reaction to a test early in the disease must not be considered as final. In undulant fever the reaction may not become positive for months. A positive reaction, unless typical, calls for confirmation. A rising titer observed over a three or four day period is usually conclusive evidence. In this day, when so many persons have been immunized against typhoid, peculiar results are encountered with the typhoid antigens. It is well to have someone experienced in this field help with the interpretation.

Infectious mononucleosis is often confused with a virus infection of the upper part of the respiratory tract and with leukemia. The blood picture in these three conditions may at some stage be similar. The heterophil antibody test will identify infectious mononucleosis rather definitely if the Davidson differential test is included.

In obscure pulmonary disease, it is not sufficient to examine sputum smears for tubercle bacilli. Culture and guinea pig inoculation must be included if the smear is negative. Six weeks ago my co-workers and I encountered 2 cases, 1 of pulmonary infection and 1 of cervical adenitis, in which no tubercle bacilli were seen in direct smear. Both test tube culture and guinea pig inoculation revealed tubercle bacilli at a later period. A search for fungi in the sputum by smear and culture sometimes is surprising in its revelation. A cold agglutination test of red blood cells may identify virus pneumonia. Sputum study for tumor cells is a new procedure. Negative observations do not rule out malignant disease, but even an occasional positive result justifies the consideration of this examination.

Cytologic Studies: The whole field of cytologic diagnosis of cancer deserves comment. I wish to emphasize that the reading of smears is a problem for the specially trained cytologist. Inexperience may lead to disastrous results and a condemnation of the whole procedure. In many communities there are specially trained persons who examine these smears. In New Jersey the Society of Pathologists offers a diagnostic service to all physicians for indigent cases, with the aid of the American Cancer Society and the State Health Department. Other states must do likewise. One can be instructed in collecting material. In proper containers filled with a suitable preserving fluid, the smears may be sent to any distant laboratory for examination. It is best applicable, of course, to vaginal and cervical smears, but sputum, prostatic secretions and gastric washings properly fixed may be mailed to any distant laboratory.

In examining a patient for any cause it is well for one to keep cancer in mind. Recently a man of 40 was seen in our dispensary. He had lost weight and had a cough, and by roentgenologic examination of the chest an old tuberculous process was seen. He came to the dispensary because of enlarged cervical and axillary nodes which were discharging a watery, sometimes cheesy, material. There were no tubercle bacilli seen in direct smear. Biopsy revealed Hodgkin's disease. He is improving with nitrogen mustard therapy alone. A woman suffering from diabetes was in the hospital for insulin standardization. She had a coughing spell and spat up a little fresh blood. The curious intern looked in her pharynx with a mirror and discovered what later turned out to be a lymphosarcoma of the lingual tonsil. A dentist, consulted because of ulcerative gingivitis, noted the widespread character of the lesion and sent the patient to a laboratory for a blood cell count. The patient had acute leukemia in an early stage.

Rh Typing: It is advised that the Rh type be accurately determined for all patients for whom transfusion is contemplated. It is imperative that the Rh type of every female patient be considered before a transfusion is administered. A single Rh-positive transfusion in an Rh-negative female patient may sufficiently immunize her so that her first born will show the disastrous effect of erythroblastosis. It is fortunate that all Rh-negative persons are not good reactors and that probably in not more than 1 in 25 will Rh antibodies develop, but the test is so simple that one is not justified in jeopardizing a woman's first born by an improper blood transfusion. For the same reason, all pregnant women should have Rh tests and the Rh antibody titer should be determined in those who are Rh negative. If the physician is properly forewarned he may save the life of a baby that might otherwise die of erythroblastosis.

Contradictory Observations at Autopsy: Autopsy may prove that the clinical diagnosis was, no matter how well founded, incorrect. I examined a woman for a county physician. She was a farm woman who had gone out to feed her mule in the early morning. When she did not return to the house on time her family searched and found her in the stall with a gash in her forehead. Death was attributed to fracture of the skull caused by the kick of a mule. Autopsy showed that she had a ruptured dissecting aneurysm of the aorta. She was as good as dead when she fell. If the mule kicked her, it was little more than a tap, for there was no fracture, not even subperiosteal hemorrhage. In another instance a young woman had a criminal abortion performed and, with her friend, went to a resort hotel to recuperate. After an afternoon on the beach she went to bed. The next morning her friend awakened to find her dead. Autopsy revealed no evidence of septic endometritis, but fulminating cerebrospinal meningitis with extensive adrenal hemorrhage. In another instance, a man died suddenly in a rural area; the local county physician performed an autopsy and, finding white kidneys, suspected bichloride poisoning. He sent the kidneys to an expert in medicolegal pathology who found only leukemic infiltration. The man had never had the advantage of a blood cell count during life.

## CONCLUSION

Considerate use of the laboratory will increase diagnostic accuracy and may shorten the length of illness.

---

**Tuberculosis in Persons Over Forty.**—There is a rather widespread clinical impression that pulmonary tuberculosis rarely makes its appearance after the age of thirty. For example, in the most recent edition of an outstanding textbook of medicine the following statement is found in the section on tuberculosis: "Those who have lived to the fourth decade without the appearance of a pulmonary lesion seldom develop the disease." Nevertheless, it is the impression of many phthisiologists that the first roentgenographic evidence of significant pulmonary tuberculosis after thirty, and even after forty, is not at all a rarity today. For instance, of the 344 cases of incipient pulmonary tuberculosis recently reported by Reisner, 17 developed after the age of forty. It was thought worth while, therefore, to report an additional 5 cases of incipient pulmonary tuberculosis in persons over forty years recently observed by the author. —Chaves, Aaron D., Incipient Pulmonary Tuberculosis in Persons Over Forty, *The American Review of Tuberculosis,* May 1949.

# NONPARALYTIC POLIOMYELITIS AND MUMPS MENINGOENCEPHALITIS

## Differential Diagnosis

LAWRENCE KILHAM, M.D.
JEANETTE LEVENS, M.P.H.
and
JOHN F. ENDERS, Ph.D.
Boston

The unequivocal diagnosis of nonparalytic poliomyelitis is difficult to achieve, since its signs and symptoms are often those associated with aseptic meningoencephalitis, and for this syndrome there may be a variety of causative agents. The most direct evidence of nonparalytic poliomyelitis which can be obtained at present consists in the isolation of the virus from the stools or pharyngeal secretions in suspected cases.[1] But the isolation of the agent from such sources cannot be regarded as entirely conclusive, and the procedures involved are intricate, time consuming and expensive. They cannot, therefore, be used as routine. The diagnosis, accordingly, is often made on epidemiologic data taken together with the clinical observations. Epidemiologic evidence, however, is intrinsically circumstantial and hence can be considered only as presumptive in character.

In contrast to the agent of poliomyelitis, the role of certain other viruses in aseptic meningoencephalitis may be established more easily by laboratory methods.[2] Of these the mumps virus is often encountered.[3] Since the development of the complement fixation test for the diagnosis of mumps infection, some other investigators [4] have obtained positive reactions for mumps with serums of patients who, on clinical and epidemiologic grounds, were regarded as having nonparalytic poliomyelitis. In view of these observations and the general considerations in respect to the varied causation of aseptic meningoencephalitis to which we have already referred, a number of cases occurring in the vicinity of Boston during July, August, September and October of 1948, with the diagnosis of nonparalytic poliomyelitis, have been studied by means of the complement fixation [2] and antihemagglutinin tests [6] for mumps. When results of these tests indicated that mumps virus was the cause of the infection, attempts were made to isolate it from the spinal fluid. The results and, for the purpose of comparison, epidemiologic data indicating the relative incidence of epidemic parotitis and paralytic poliomyelitis in the community during the period of study are presented in this communication.

### RESULTS OF SEROLOGIC TESTS FOR MUMPS INFECTION AND ATTEMPTS TO ISOLATE THE VIRUS

Mumps complement fixation and inhibition of hemagglutination (antihemagglutinin) tests were carried out on pairs of serum specimens in acute and convalescent stages derived from 17 patients whose illness was diagnosed by members of the hospital staff, either tentatively or finally, as nonparalytic poliomyelitis. Attempts to demonstrate mumps virus were made by inoculation of the spinal fluid into the amniotic sac of chick embryos. The slight modification of the technic employed in this procedure has been recently described.[6] From the results of the serologic tests which are summarized in table 1, it was concluded that in 6 of these 17 cases (cases 1 through 6) the virus of mumps was responsible for the disease. Thus, during the course of illness in all of them a significant increase in complement-fixing antibody (8 times or more) was demonstrated. Comparable increase in antihemagglutinins was also revealed. Confirmatory of the serologic observations was the demonstration of virus in specimens of the spinal fluid obtained from 3 of the patients. On the other hand, it is evident that the serologic tests on the pairs of serum in 10 of the remaining 11 cases failed to show any change during the course of the disease in the concentration of mumps antibody (cases 8 through 17). In case 7 acute phase serum was not available, but the low titers of the convalescent phase serum afford presumptive evidence that this patient had recently not been infected by the mumps virus. It would seem, therefore, that this agent was not involved in these 11 cases. This conclusion is likewise supported by our failure in 3 cases of paralytic poliomyelitis to demonstrate a change in the concentration of mumps antibody during the course of the disease and convalescence. Moreover, the spinal fluid obtained in 2 of these cases failed to produce mumps infection in chick embryos.

### CLINICAL OBSERVATIONS

No essential difference was observed between the clinical signs and symptoms presented by the two groups of patients. In none was enlargement of the salivary glands detected, although 1 patient among those with the diagnosis of mumps meningoencephalitis had orchitis five days after he was admitted to the hospital and 5 of this group gave a history of exposure to mumps parotitis three to four weeks before the onset of their illness. Lethargy, headache, nausea, vomiting and nuchal rigidity occurred in both groups. One of the patients, who had positive serologic reactions for mumps and subsequently visited a clinic for the aftercare of poliomyelitis, exhibited weakness of the anterior part of the neck and abdominal muscles. In none of the remaining 16 cases did definite muscle weakness develop. The mean duration of illness of the group with mumps meningoencephalitis was 8.5 days; that of the other group was 6.5 days.

### CHANGES IN THE CEREBROSPINAL FLUID

Leukocyte counts of the cerebrospinal fluid from the 6 patients with mumps meningoencephalitis all exceeded 200 per cubic millimeter, and the proportion of lymphocytes was at least 90 per cent. In 4 of them the total protein exceeded 40 mg. per hundred cubic centimeters. In contrast, in most cases in which the virus of mumps was not involved there were lower total protein concentrations and leukocyte counts. The observations in the 6 cases of mumps meningoencephalitis also were characteristic of a larger series which was recently studied.[7] But it must be understood that they are not always encountered in this disease, while occasionally in cases in which the condition is not caused by the mumps virus (case 16, table 1) the leukocyte count and total protein may be elevated to a degree comparable to that usually observed in mumps meningoencephalitis. It is, therefore, obviously impossible to make a conclusive etiologic diagnosis on the basis of changes in the cerebrospinal fluid. Such changes, however, may help the clinician in making a provisional diagnosis.

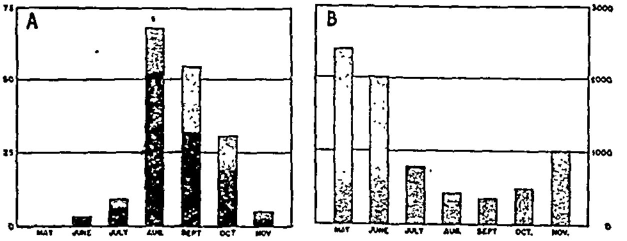
### INCIDENCE OF NONPARALYTIC POLIOMYELITIS AND MUMPS PAROTITIS IN MASSACHUSETTS

In regard to the results of the laboratory tests described, it is relevant to compare the incidence of paralytic and nonparalytic poliomyelitis and of mumps

---

7. Kilham, L.: Isolation of Mumps Virus from the Blood of a Patient, Proc. Soc. Exper. Biol. & Med. 69: 99-100, 1948.

parotitis reported to the Department of Health of Massachusetts in recent years. Within the Commonwealth the reporting of cases diagnosed as nonparalytic poliomyelitis first became routine in 1935.[8] From that time until the end of 1945, the disease in approximately 33 per cent of all reported cases of poliomyelitis was, in an average year, designated as nonparalytic. Subsequently this proportion increased steadily to reach a maximum of 66 per cent in 1948. It is remarkable that the year 1948 was characterized by the lowest incidence of the paralytic form recorded in the last six years. This year has also been distinguished, as indicated in the figure, by an unusual incidence of mumps. Indeed, from June through November, the only period in which poliomyelitis was reported to any appreciable extent, the monthly incidence of mumps exceeded that for any comparable period since the reporting of the latter began in 1916. The disparity between the reported incidence of the two forms of poliomyelitis and the parallelism between the incidence of the nonparalytic type and mumps suggest that a significant number of the cases in which the diagnosis was given as poliomyelitis without paralysis might have been cases of mumps meningoencephalitis.



*A,* incidence of poliomyelitis, nonparalytic (black bar) and paralytic. *B,* incidence of mumps. (Massachusetts, 1948.) The vertical values show the number of cases.

Additional support for such an inference is offered by the difference between the age distribution in paralytic and nonparalytic cases. Horton and Rubenstein[9] noted that in Massachusetts nonparalytic poliomyelitis is reported most frequently in the age group 5-15 years, whereas the incidence of paralytic cases is highest among the age group 0-4 years (table 2). It would appear, therefore, that the age distribution of nonparalytic poliomyelitis is similar to that of mumps and not to that of the paralytic form.

## COMMENT

The serologic and virus isolation studies which have been summarized indicate that the disease in 6 of 17 hospitalized patients diagnosed clinically as nonparalytic poliomyelitis was actually infection with the mumps virus in which salivary gland involvement was not evident. Although the number of patients is small, these observations are sufficient to show that it is frequently impossible to identify the nature of the infectious agent in either of these conditions on clinical and epidemiologic criteria alone.

As yet no laboratory method for the routine diagnosis of nonparalytic poliomyelitis is available. On the other hand, procedures have recently been devised, consisting either in the demonstration of the development of specific antibodies or in the isolation of the agent during the course of the illness, whereby meningoencephalitis due to mumps can be usually differentiated. Since mumps meningoencephalitis without parotitis is by no means rare, it would seem that whenever possible the diagnosis of nonparalytic poliomyelitis should be withheld until laboratory tests for mumps meningoencephalitis have been carried out.

The results of such tests are most often positive in patients exposed to mumps who present signs and symptoms of meningeal irritation and who exhibit a high leukocyte count with a high proportion of mononuclear cells in the spinal fluid. But it should be emphasized that the serologic reactions may also indicate that the mumps virus is occasionally involved even when the leukocyte count is under 100 per cubic millimeter and when no definite history of exposure to mumps can be readily obtained.[3]

From the epidemiologic point of view, a diagnosis of nonparalytic poliomyelitis may be suggested if other members of the family or group concurrently have the paralytic form. Without a definite history of this sort, however, the mere occurrence of aseptic lymphocytic meningoencephalitis during the late summer and early fall, when poliomyelitis may be epidemic, is insufficient to warrant even a tentative diagnosis of the nonparalytic form of the disease. Thus, not only various types of mosquito-borne encephalitis may appear at times in certain areas, but also, as we have shown in this communication, cases of mumps meningoencephalitis may occur. With respect to the seasonal association of the latter with nonparalytic poliomyelitis, it is perhaps pertinent to point out that enlargement of the salivary glands may possibly develop less frequently in mumps infections during the summer months and that during this season the incidence of meningoencephalitis without parotitis may be relatively greater. Observations in support of this conjecture have been presented elsewhere.[7]

TABLE 2.—*Age Distribution of Poliomyelitis, Paralytic and Nonparalytic* *

| Age Group, Yr. | Paralytic | Nonparalytic | Total |
|---|---|---|---|

## SUMMARY

Among 17 hospitalized patients given the diagnosis of nonparalytic poliomyelitis, 6 appeared to have mumps meningoencephalitis, as indicated by the results of serologic tests. The virus was recovered from the spinal fluid of 3 of these patients. The unequivocal diagnosis of nonparalytic poliomyelitis is at present difficult or impossible to make on the basis of clinical, laboratory and epidemiologic observations.

# DIAGNOSTIC CLINIC FOR REHABILITATION

A. R. SHANDS Jr., M.D.
Wilmington, Del.

With insufficient information and an inaccurate diagnosis a patient may start a program of rehabilitation totally unsuited to his handicap; hence the first major division in the organization of services for the rehabilitation of the handicapped is the diagnostic clinic. The physical qualities, mental characteristics and vocational abilities of the patient must be determined, recorded and evaluated before treatment is started. Then and then only can a rational plan leading to the restoration of this handicapped person to the best possible physical, economic and social status be formulated. The purpose of this paper is to present a few ideas on the organization and value of the diagnostic clinic for rehabilitation with several related thoughts on other problems of rehabilitation.

In the practice of curative medicine, if the physician is not certain of a diagnosis, the patient is sent to a clinic in which there are medical specialists with x-ray and laboratory facilities at their command for special examinations of the blood, urine, heart, chest, skeletal framework and the like. This is the medical diagnostic clinic, and it is here that a complete study of the physical and mental characteristics of the patient can be made. But in this clinic there is neither the personnel nor the facilities for determining the assets and capabilities of the patient for returning to work with a handicap and a need for social adjustment. The diagnostic clinic of rehabilitation does have such personnel and facilities in addition to those required to make a medical diagnosis. In this clinic for rehabilitation there must be determined such factors as the extent and character of the patient's work experience; his adaptabilities and aptitude for further education and work with his handicap; his physical achievements for daily living; the effect of his illness and inactivity on his mind, and his personality traits, which some say constitute the greatest single factor in the success or failure of rehabilitation. A careful appraisement should be made of his attitude toward a complete recovery and social adjustment and whether he has the will to do or an ability to make "the best of what he has left." It has been said that the normal person goes through life utilizing only about 15 per cent of his reserves and resources. The handicapped definitely learn quickly to draw on their reserves and resources. A person can live satisfactorily with one lung or one kidney, and he can live satisfactorily with half or less than half of normal muscle strength. By developing the remaining muscles or parts of muscles and learning how to substitute what he has left for what he had before, the patient can adapt himself to nearly all of the physical demands involved in independent living. These and many others are the traits and characteristics of the disabled man which must be ascertained in the rehabilitation diagnostic clinic.

It must be remembered that rehabilitation is an individualized process and will never lend itself to fixed and stereotyped programs. Each case represents a separate problem, which has to be studied and judged on its own merits; hence the need for an accurate diagnosis. Too much emphasis cannot be placed in the diagnostic study on a thorough and careful estimation of the emotional and mental qualities of the patient. It can be seen how unsuitable and oftentimes incorrect a plan of rehabilitation might be started on without a satisfactory understanding and evaluation of all of these factors, and how the diagnostic clinic represents the starting point and key to successful rehabilitation.

## DIVISIONS OF REHABILITATION DIAGNOSTIC CLINIC

The rehabilitation diagnostic clinic (chart) should have two divisions: the medical division, in which the extent and character of the disability will be determined and evaluated, and the achievement test division, in which the abilities of the handicapped for work and to meet the demands of daily living will be determined and evaluated. The director should be fully acquainted with all the problems of rehabilitation and may be either a physician or a layman.

*Medical Division.*—The medical division of the diagnostic clinic should have a physician as director, for a director with medical training is best qualified to interpret and evaluate the examinations, special studies and laboratory tests. There should be three branches of this division, namely: medical consultants, psychosocial and physical medicine. In the medical consultants branch there should be a consulting staff representing all medical and surgical specialties not included in the other two branches of the division and sufficient laboratory facilities for the determination of the more common laboratory tests. In the psychosocial branch there should be a psychiatrist who has a special interest in psychosomatic problems and a medical social worker who has had special training in psychiatry. The social worker who is trained to investigate the home conditions of the patient, his economic status and his relationship to his family, to his relatives, to his friends and to his business or working associates will render valuable assistance in the final appraisal of the case. In the physical medicine branch there should be a physiatrist, who is the physician trained in physical medicine, and a physical therapist, who has had special training in muscle examinations and determination of joint motion. A high percentage of patients in need of rehabilitation have orthopedic conditions. In 1940 there were estimated to be over 2,500,000 persons in the United States with orthopedic handicaps in need of rehabilitation, 13 per cent of whom were decidedly disabled. In all of these patients there is some involvement of muscles and joints which must be properly examined and their functional value estimated before

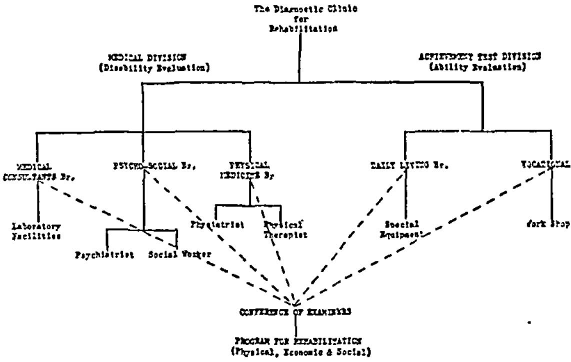

Chart showing organization of a rehabilitation diagnostic clinic.

a sound program of rehabilitation can be decided on; hence the need for the special training of the physical therapist.

*Achievement Test Division.*—The achievement test division should be headed by a director who has had training and experience in vocational rehabilitation. There should be two branches, namely, daily living and vocational. In the daily living branch there should be determined what the patient can do with his disability in meeting the physical demands of daily life. The equipment in this branch must be especially selected and be such apparatus as is necessary for the ascertainment of this information. An accurate determination of these tests is most important for the severely handicapped. It has been estimated that there are thirty-seven basic skills involved in the achievement tests which must be mastered in order to cope with the commonplace activities of living, such as dressing, eating, washing and walking up and down stairs. These are not the specialized skills necessary for a vocation, but only those which have to be used in daily living. There have been seventy-two achievement tests for daily living described for the paraplegic patient,[1] activities which he should be able to carry out successfully every day. Without these observations a suitable program of rehabilitation cannot be planned, for first attention in all rehabilitation programs must be given to teaching the patient how to adequately take care of himself in daily life.

In the vocational branch, there should be determined the work capabilities of the patient as well as what his adaptabilities are for all types of work. One can do this only by observing the patient in a shop and seeing how he handles the tools to which he has been accustomed. If he cannot use these tools, a plan must be worked out for him to be taught to use the tools of the work he can perform with his handicap. The equipping of this branch must be carefully planned and should include all equipment necessary to execute the work of the more common vocations. In one of the large Army hospitals during the last war it was determined that there were fifteen primary vocational interests of the handicapped with a distinct preference for mechanical occupations. Kessler[2] stated, ". . . given a sound mind and ordinary intelligence there is no trade and vocation in which able bodied persons may engage that cannot be carried on by a physically handicapped person, if some consideration is made for his disability." This has been the experience in every rehabilitation clinic.

## PERSONNEL

In all programs of rehabilitation the instruction of the faculty, i. e., the teacher and the examiner, is paramount and should be one of the first steps in the establishment of both the diagnostic clinic as well as the therapeutic service. This faculty must be taught to observe carefully what the patient does, what the patient says and what his reactions are to various situations. They should be what have been termed "watchdogs of reality." There cannot be one fixed plan of training for the handicapped even though the handicaps may fall apparently into certain groups of physical disability. There must evolve from the diagnostic studies of every patient a clear understanding and appreciation of what he was before his handicap, what he is with his handicap and what he can be in the future. All patients who are handicapped have deep psychologic scars. The mental is always associated with the physical in injury and disease. The plan to heal the psychologic scar may be often more important than the plan to heal the physical scar. This plan must be formulated after very careful personality and emotional studies of the patient; it should include a program which will correct faulty personality traits, maintain good personality traits and stabilize the emotional state.

The personnel of the branches in both divisions of the diagnostic clinic should have a basic knowledge of the psychology involved in the evaluation and handling of the disabled. It cannot be emphasized too strongly that throughout all phases of rehabilitation everyone should be alerted to make note of the psychologic characteristics of the patient. Often it may be that the examiner who is determining an achievement test will pick up some remark or some attitude of the patient toward what he is doing which will be of utmost importance in the final evaluation of the case.

## INTEGRATION

When the reports of all of the examinations, studies, tests and observations in the two divisions have been made, there should be then a full discussion of these reports by those who have been the examiners. From these discussions should develop the final plan of rehabilitation for this particular patient. Before the final plan is decided on the vocational placement director should be consulted in order to determine the demand for different types of employment in the community. This demand should be taken into consideration before one renders a final decision on the type of vocational training to be given.

After the rehabilitation program of the patient, which includes vocational training, has been completed, he should be returned to the diagnostic clinic. His physical, mental and emotional characteristics should be reexamined and reevaluated. It is possible that during the period of rehabilitation many of these characteristics may have changed. Before job placement is a reality and he is "discharged to duty," if there are changes, particularly of the emotional state, these should be recognized and considered, in the final disposition of the case. From experience it is known that 10 to 25 per cent of those placed in employment by the vocational rehabilitation services do not continue on the jobs in which they were first placed. There must be an explanation for this, and it most likely is a change in the mental attitude during the period of rehabilitation. Once a handicapped person faces life as a paid professional worker, a definite barrier has been crossed. If he fails in his first job there will be an emotional reaction and a psychologic setback which will definitely make his future adjustment most difficult. With this second diagnostic survey these situations may be averted and the percentage of initial work failures among the handicapped will be decreased.

## COMMENT

A great deal of the planning and thought concerning rehabilitation is considered by many to be impractical, idealistic and to represent theory which will never work out in practice. David Livingston once said, "Out of the castles in the air come the cottages by the sea." Dreaming of ideal rehabilitation as represented by "the castles in the air" is what a great many of the workers in the field of rehabilitation may have experienced. Without dreams, however, it is certain that "the cottages by the sea," or many of the worth while attainments of life, would never be here today. But we want to be sure that we are still not in the dreaming or "the castles in the air" stage in our thinking. If we remain too long in this stage, many of our programs of rehabilitation may collapse. A balance between the visionary and the nonvisionary, the common sense workable point of view toward the situation, is what we wish to attain in our thinking. So often in the application of theory and ideals to situations dealing with patients, one completely forgets such things as what the patient thinks he himself can do, what he thinks his attainments and accomplishments can be with his disability. In planning a rehabilitation program these should always be given serious consideration. Rehabilitation or any other phase of medicine does not represent an exact science. Whenever there is an element of doubt, I strongly recommend that the physician or the rehabilitation worker lean toward the practical side, and, in this instance, it is the satisfying of the patient first in what he can or cannot do with his disability.

[2] Kessler, H. H.: Rehabilitation of the Physically Handicapped, New York, Columbia University Press, 1947, p. 30.

A word further about the importance of the patient's mental picture in the whole program of rehabilitation. This has been summed up well by Yost and Gilbreth.[3] "It's not the body, it's the man's mind which determines whether he is going to be a loafer a few years from now or not." They further state that the challenge for the handicapped man is ". . . to face that man deep within himself and find out if he wants economic independence. If the inner man is a shirker, he will shirk. But if deeper still, the inner man is a worker, he will work. If the inner man wants success in work, he will find within himself capacities such as he never realized he possessed. Like thousands who have preceded him, he may soon find that his handicap is becoming a spur he might never have found if life had been too easy." There is no doubt that if the mental wounds which have been inflicted by the physical handicap have caused the man deep within himself not to want economic independence, and have created a state of mental lethargy and despair, all attempts at rehabilitation may be futile. In any program for the handicapped from the beginning of injury or disease, especially for the disabled man who will require long term care, steps should be taken at once to prepare the man for his future and to do all that can be done, as Kessler[4] said, ". . . to immunize the patient against the virus of hospitalitis with its indolence, procrastination, and lack of ambition." If the program cannot prevent or bring him out of this state, rehabilitation will be a failure. The diagnostic clinic should help to identify these mental wounds and to determine whether the inner self in this patient really wants success. Destructive attitudes associated with physical disability may quickly take hold of the handicapped, often before either the patient or the physician realize what is happening. This is particularly true if the handicapped person feels that there is a prejudice in business and industry against him. On the other hand, the handicapped man with the proper attitude on the job who is dependable and prompt, who does not need to be told how to work and who is accurate and careful in all his work and tactful and diplomatic in conversation will succeed in spite of any disability and whatever prejudice his employer may have previously had toward disabled persons. Franklin Roosevelt has been for the past twenty years the great example of the disabled man who overcame his handicap because of great determination to overcome the defects of his disease. The answer definitely resides in the handicapped person. As it has been so aptly expressed, "It lies in his ability not in his disability." This will determine his future.

Medical knowledge is said to be at least fifty years ahead of its application. At present we possess a vast storehouse of information relating to the principles and technic of the rehabilitation of all types of handicapped persons. The basic thoughts on modern rehabilitation have been well known since World War I, but technics have changed, especially since the beginning of World War II. There is an immense job of education needed for the physicians and laiety before rehabilitation will be integrated into the everyday practice of medicine. A forward step has been made at the New York University School of Medicine in establishing a department of rehabilitation and physical medicine, where the intern, the resident and the graduate and undergraduate student are being taught the problems of handicapped persons and their solution. More physicians are beginning to realize that the best care of the patient is the total care, that the mental, the social and the vocational recovery is as important as the physical recovery and that this can best be obtained in the intelligently planned program of rehabilitation. Perhaps it can be said that we have experienced, from 1918 to 1948, thirty of the fifty years necessary for the application of this medical knowledge and, through international meetings such as this and the establishment of a department of rehabilitation in all of our medical schools as has been done at New York University, the span of the next twenty years may be shortened.

## CONCLUSION

It should be reemphasized that the starting point and key to all successful rehabilitation services is the diagnostic clinic. It must be appreciated that its scope is far larger than that of the medical diagnostic clinic which forms only one part of the diagnostic clinic for rehabilitation. But it must be remembered that rehabilitation is in its infancy and many changes will be made as this new specialty grows into adolescence and young adult life. Montaigne[5] said, "Arts and Sciences are not cast in a mould, but are formed and perfected by degrees, by often handling and polishing." This is what is taking place in rehabilitation today. It is being changed; it is being perfected by the frequent changing of technics which are found to be unsatisfactory and by the polishing of the good technics which are found to be satisfactory, and in the course of time there will evolve a service in medicine in which all will have confidence. Rehabilitation may now be in the same stage of development in which orthopedic surgery was in the second half of the last century, when Lewis A. Sayre[6] of New York, the first professor of orthopedic surgery in the United States, wrote, "At present orthopaedic surgery is but imperfectly understood amongst us and but few feel competent to practice it. It shall be our endeavor so to develop this department of surgery that no surgeon hereafter shall feel himself fairly educated in his profession until he has also mastered this particular branch." There is no doubt at present that rehabilitation is poorly understood. Few of us feel competent to practice it, and there is a vast job of education needed to bring the importance of the knowledge newly gained to the mind of the average physician. With greater experience, there will come a time when all physicians will feel a degree of confidence in what can be done for their patients with good rehabilitation and will not consider themselves educated until they know the technics and are masters of the practice of this "third phase of medicine."

It has been shown in a number of experimental infections[1] that the amount of penicillin necessary for cure increases with the number of organisms inoculated. Thus, in white mice infected with pneumococci, the single curative dose of aqueous penicillin G increased in one experiment from 5 to 260 mg. per kilogram of body weight as the inoculum was increased from 15 to 200,000 organisms.[1c]

Corollary to these observations, it was found that the longer the interval between inoculation and treatment, the more drug was required for cure. Presumably because of the interim multiplication of organisms, effectively bactericidal levels had to be provided for longer and longer aggregate periods in order to kill enough of the bacteria to effect cure. In syphilitic rabbits, the 50 per cent curative dose of penicillin (in oil and wax) 4 hours after intratesticular inoculation with 2,000 organisms was 1,420 units per kilogram of body weight; but by the second week it had increased to 13,600 units per kilogram, and by the sixth week to 59,000 units per kilogram.[1b] In rabbits infected with 2,000 beta hemolytic streptococci, the single curative dose of penicillin G increased progressively from 0.29 mg. per kilogram at the time of inoculation to 40 mg. per kilogram within 6 hours, and to more than 1,000 mg. per kilogram within 24 hours. Similar results were obtained in other experimental infections.[1c]

These large differences between the amounts of penicillin required to effect cure with young and old infections were so pronounced as to suggest that penicillin might be an effective agent for the prevention as well as the cure of bacterial infections.[1c] Specifically, since approximately 100,000 units of penicillin G given as a single injection in aqueous solution cures more than 90 per cent of established gonococcic infections, it seemed possible that as little as 5,000 to 10,000 units might suffice if the disease were treated early during the incubation period, a few hours after exposure; in such circumstances it seemed possible that a single tablet of penicillin taken by mouth might prove to be an effective abortive procedure.

The present study was therefore undertaken to study the efficacy of a single tablet of penicillin, taken by mouth, in the prevention of gonococcic infection. The subject population consisted of a group of male military personnel, varying in number from 200 to 400, with a high venereal disease rate and under reasonably close medical supervision. The subjects were at first divided into two groups. One group was given a single tablet of penicillin G as the men returned from shore leave, whether or not there had been exposure[2] and regardless of the interval which had elapsed since that exposure. The second group was given a tablet of similar appearance, but containing no penicillin. A generally successful attempt was made to have the penicillin taken at the time of issue and under observation. The subjects were at first not apprized of the purpose of the study, other than that it was designed to study methods of controlling "infections"; and no attempt was made either to change previous routine with respect to venereal disease prophylaxis or to determine what other prophylactic agents, if any, had been used. The men were further not informed that there were two types of tablets. The duration of shore leave varied from a minimum of 2 hours to a maximum of 22 hours. The mode was approximately 6 to 8 hours, the largest single group leaving the station between 4 and 8 p. m. and returning at 12 to 2 a. m. The time which had elapsed between possible exposure and the ingestion of penicillin was considerably less than the duration of the leave and is estimated to have averaged approximately 2 hours.

For reasons which are not germane to the present study, it was not possible to keep as close a control on leaves as is usually the case in a military installation. There is reason to believe that there were a large number of unrecorded liberties and that in some instances these were unauthorized. Further, and perhaps because of the limited information which they were given as to the purpose of the study, not all of the subjects were wholly cooperative in the first two experiments. Because it was difficult to maintain an adequate 24 hour supervision of the returning personnel, some of the subjects in the experimental group failed to take the penicillin prophylaxis, without appropriate record being made of that omission. The complications[1b] thereby introduced into the statistical evaluation are discussed in the fourth (§) footnote to table 1.

## RESULTS

Experiment 1. *Effect of 100,000 Unit Tablets of Penicillin on the Incidence of Gonorrhea.*—In the first sixteen weeks of the study, the men in the experimental group were given a single 100,000 unit tablet of peni-

[2] It is estimated that in the particular study group there was sexual exposure in more than 50 per cent of all liberties.

cillin G as the prophylactic (or more correctly, abortive) procedure, administered as the men returned from shore leave. The results over that period are summarized in table 1.

In the control group receiving no penicillin, there were a total of 35 cases of gonorrhea over the sixteen week period. This is an incidence of 610 cases per thousand men per year, and 12.2 cases per thousand liberties. In addition, there were 6 cases in men supposed to have received penicillin after each liberty but who, for a variety of reasons, detailed in the second footnote of table 1, are known not to have taken the prophylaxis.

TABLE 1.—*Prevention of Gonorrhea with a Single Tablet of Penicillin Taken by Mouth (Results When Patients Were Divided into Two Equal Groups, One Receiving Penicillin and One Receiving a Placebo)*

| | Experiment 1 (16 Weeks) 100,000 Units | | Experiment 2 (8 Weeks) 250,000 Units | |
|---|---|---|---|---|
| | Control Group | Experimental Group, Receiving Penicillin | Control Group | Experimental Group, Receiving Penicillin |
| Number of subjects*...... | 176-195 | 151-213 | 137-217 | 87-141 |
| Number of liberties........ | 2,871 | 3,218 | 745 | 569 |
| Number of cases †......... | 35 | 5 | 8 | 1 (?) ‡ |
| Incidence of gonorrhea.... per 1,000 men per year § ¶ | 610 | 105 | 325 | ... |
| Incidence of gonorrhea.... per 1,000 liberties | 12.2 | 1.8 | 10.8 | ... |

* The figures in this row represent the variations in the total number of subjects in each group during single 4 week periods of the study. Men were included even though they may have been in the study or in the group for only a fraction of that period. This figure is therefore somewhat greater than the average number of subjects in the study. In consequence, the rates per thousand men per year given in the table are somewhat lower than was actually the case.

† These figures do not include a total of 9 cases of gonorrhea which developed in men supposed to have taken penicillin, but who are known definitely not to have taken the drug after the leave in which the infection was contracted, either because they refused, because the leave was unauthorized or because of the laxity of the watch in charge of dispensing tablets. These cases should obviously not be included in assessing the efficacy of the procedure. There must, however, have been many others in the experimental group, supposed to have taken the drug, who failed to do so and nevertheless escaped infection. The total of 5 failures charged to the experimental group receiving 100,000 units of penicillin includes 3 cases in which there was no record on the individual card that the penicillin had been taken, and which may therefore not have been penicillin failures. They have nevertheless been treated as failures in the calculations because there was no proof that the tablets had not been taken.

‡ This case developed in a subject 5 days after exposure, and after the supposed ingestion of a 250,000 unit tablet. The subject denied having received a pill, despite the entry on the record.

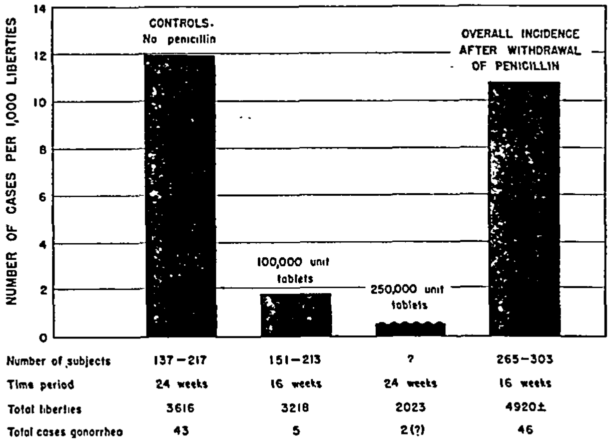
§ Some of the men supposed to receive penicillin actually failed to do so, and in calculating these rates an attempt has been made to correct for these omissions. If in a given month there were, for example, 10 cases in a control group of 200 men, with a total of 500 liberties, and if in the same period there were, for example, 1 case in the supposedly experimental group who failed to take penicillin, it is assumed in calculating the rates that 1/10 × 200 = 20 men in the experimental group had failed to take the drug, and that this had occurred in a total of 1/10 × 500 = 50 liberties. The values so calculated have been subtracted from the totals in the experimental group in calculating the rates per thousand men per year and per thousand liberties. The correction is obviously approximate only, but to exclude the cases developing in subjects who had failed to take penicillin without at the same time changing the base figure would result in rates biased in favor of the prophylactic procedure.

¶ Mr. Jerome Cornfield and Mr. Nathan Mantel, of the Office of the Statistical Coordinator, Division of Public Health Methods, assisted in calculating these rates and making the appropriate corrections.

In the experimental group, presumably receiving penicillin, there were 5 cases (105 per thousand men per year, and 1.8 cases per thousand liberties, third footnote of table 1). In 3 of these 5 failures, there was no entry on the card that the subject had received penicillin, and there is therefore reason to suspect that no drug was taken. These cases have, however, been included in the failures of table 1 and in the foregoing estimated rates.

The question may be raised as to whether the apparent efficacy of the procedure was due to the fact that the men received a tablet after each liberty and that the infection may therefore have been aborted not by a single tablet but by 3, 4 or even 5 such tablets taken in succession. However, in 46 per cent of the liberties in the experimental group, a minimum of 3 days elapsed before the next liberty, and in 34 per cent there was a minimum of 4 days. In the entire group, the average number of liberties was 1.1 per week, and the average interval between liberties was 6.3 days. In view of the fact that gonorrhea usually develops in 3 to 5 days,[3] it follows that on the average only 1 to 2 tablets would have been taken during the incubation period of the disease. It seemed clear that this amount of penicillin taken by mouth, usually within less than 4 hours after exposure, had materially reduced the incidence of gonorrhea.

EXPERIMENT 2. *Effect of 250,000 Unit Tablets of Penicillin on the Incidence of Gonorrhea.*—On the termination of this first experiment, the size of the tablet was increased to 250,000 units, the men remaining in the same two groups.[4] The incidence in the control group continued at a high level, 8 cases developing in an eight week period after 745 liberties (325 cases per thousand men per year, and 10.8 per thousand liberties). In addition, there were 3 cases in subjects supposed to have received penicillin, but who took unauthorized leave and did not receive penicillin after exposure. In the experimental group receiving penicillin, there was only 1 case in 569 liberties; this subject denied having received a tablet, despite the entry on his card.



Graphic depiction of the prevention of gonorrhea with peroral administration of penicillin.

The results obtained in the 24 weeks of these first two experiments are summarized in the left-hand portion of the figure, which shows graphically the influence of the 100,000 and 250,000 unit tablets on the incidence of gonorrhea. If one combines all the data, then the following results are obtained: (*a*) In the control group a total of 43 cases developed after 3,616 liberties, an incidence of 11.9 cases per thousand liberties, and 508 cases per thousand men per year. (*b*) In the experimental group receiving penicillin at a dosage of 100,000 units, there were 5 cases after 3,218 leaves (1.8 cases per thousand leaves, and 105 per thousand men per year). The probability that this difference between the control and experimental groups could occur by chance alone is less than one in a million.[5] (*c*) In the experimental group receiving 250,000 unit tablets, there was 1 questionable failure after 569 leaves.

---

[3] Pelouze, P. S.: Gonorrhea in the Male and Female, ed. 3, Philadelphia, W. B. Saunders Company, 1939.

[4] Midway in this period, the total number of subjects in the station, and available for the study, was suddenly reduced from 361 to 224.

EXPERIMENT 3. *Results When 250,000 Unit Tablets of Penicillin Were Taken on a Voluntary Basis.*—In the light of the promising results obtained in these first two experiments, covering a 24 week period, an attempt was made to determine the degree to which gonorrhea could be controlled by peroral penicillin prophylaxis taken voluntarily. The men were now informed as to the purpose of the study, that they had hitherto received two types of tablets, only one of which was effective, and that although no attempt would be made to impose the administration of the tablets, they would be available as desired on return from leave.

In such a volunteer study, it is a reasonable presumption that most of those requesting penicillin after a shore leave had actually been exposed. By the same token, of those who did not request prophylaxis a large proportion either had not been exposed or had been exposed only to their regular sex partner. This voluntary selection clearly biased the data against the penicillin prophylaxis.

As is indicated in section B of table 2, there were a total of 14 cases of gonorrhea over the 16 weeks of this voluntary study. Thirteen of these cases occurred in subjects who had chosen not to take prophylaxis on returning from the leave in which the disease was contracted. This represents an incidence of 3.9 cases per thousand "unprotected" leaves. In the 1,454 leaves protected by penicillin there was only 1 case, and in this instance the subject was absent without leave for 5 days in the 7 day interval between the "protected" leave and the date the symptoms appeared, with several "unprotected" exposures during that interval.

TABLE 2.—*Prevention of Gonorrhea with Peroral Penicillin (Results When 250,000 Unit Tablets Were Made Available on a Voluntary Basis to All Requesting It After Exposure)*

| | A | B | | C |
|---|---|---|---|---|
| | Previous Experience Over 24 Week Period in Control Group Not Receiving Penicillin | Results During 16 Week Period of Voluntary Prophylaxis | | Results in Following 16 Weeks After Penicillin Was Withdrawn |
| Number of subjects | 137-217 | 331-339 | | 265-303 |
| Total number of liberties | 3,616 | 4,827 | | 4,920 ± * |
| | | Liberties not protected by prophylaxis † | Liberties protected by single 250,000 unit tablet ‡ | |
| Number of liberties | 3,616 | 3,373 | 1,454 | 4,920 ± |
| Number of cases of gonorrhea | 43 | 13 | 1 (?) § | 46 |
| Incidence: cases per 1,000 liberties | 11.9 | 3.9 | 1 | 10.7 ± |

* Based on average figure in the first 24 weeks of the study of 3.8 liberties per man per 4 weeks.

† These represent liberties at which (*a*) there had definitely been no exposure, (*b*) exposure had been marital partner only or (*c*) there had been extramarital exposure, but the subject had elected not to take the penicillin tablet.

‡ Since the men were at this time informed as to the purpose of the tablets, there had probably been exposure on essentially all the liberties after which penicillin was requested: one would therefore have expected an even higher rate in this group than in the unselected experience of the first row.

§ This questionable failure represents a man who had gonorrhea 7 days after receiving penicillin prophylaxis, but who had, in the meantime, been on unauthorized leave for 5 days, with repeated exposures.

EXPERIMENT 4. *Results When Penicillin Was Withdrawn.*—After this 16 week period of voluntary prophylaxis, the penicillin tablets were withdrawn. As shown in the right-hand portion of the figure, the rates promptly returned to their "normal," prestudy level. Over the following 16 weeks, during which the station complement varied from 265 to 303 men, there were a total of 46 cases of gonorrhea. This represented an incidence of 525 cases per thousand men per year, and an estimated[6] *incidence of 10.7 cases per thousand* liberties, essentially the same as that observed during the controlled experiment in the men who received a placebo instead of penicillin. It seemed clear that the opportunity for infection had not changed materially during the period covered by the penicillin experiment and that the reduced incidence in those taking the drug (figure) could with some assurance be ascribed to the penicillin and not to some extraneous factor.

## COMMENT

1. *Efficacy.*—The foregoing data, graphically summarized in the figure, indicate that the ingestion of a single 100,000 to 250,000 unit tablet of penicillin may constitute a simple method for prevention of gonorrhea, one which can be used effectively for a number of hours after exposure and which does not have some of the undesirable features which attend the use of local prophylaxis. Under the conditions of the present study, the 100,000 unit tablet caused an 85 per cent reduction in the incidence of gonorrhea (5 cases in 3,218 liberties, as compared with 43 in 3,616 unprotected liberties) and the 250,000 unit tablet was more than 90 per cent effective (2 questionable cases in a total of 2,023 liberties).

The maximum period after exposure for which penicillin at those dosage levels could be relied on to abort gonococcic infection remains to be determined. The organisms multiply so rapidly and the incubation period of the disease is so short, that those doses may remain effective only if taken within 2, 4 or 6 hours, after which larger or multiple doses may become necessary. This is clearly indicated by the study of Campbell, Dougherty and Curtis,[7] who found in a second group of men that a single 200,000 unit tablet of penicillin taken on average of 14 hours after exposure caused approximately a 58 per cent reduction in the incidence of gonorrhea.

---

[5] A total of 43 infections were observed after 3,616 liberties in the control group, and 5 infections after 3,011 liberties in the experimental group (corrected as indicated in fourth [§] footnote of table 1 for those who failed to take prophylaxis). If the rate per thousand liberties was the same among the controls and the experimental group, the expected number of infections would have been 26 among the controls and 22 among the experimental subjects instead of 43 and 5, respectively. The chi square test indicates that a difference of this magnitude or greater between the expected and actual number of infections could have occurred by chance less than one time in a million. Even if the infections where prophylaxis is known not to have been taken are included as failures in the experimental group, the difference between the experimental and control groups is still highly significant. So computed, there were 14 infections in 3,787 liberties in the experimental group, and 43 infections in 3,616 control liberties. Were there no difference in the rates in the two groups, the expected values would have been 28 and 29, respectively. A difference between the actual and expected values of this magnitude or greater could have occurred by chance alone about once in thirty thousand times.

[6] Assuming that the number of liberties per man remained at the level of 3 per week, the average of the preceding 40 weeks of the study.

[7] Campbell, V. W. H.; Dougherty, W. J., and Curtis, C. E.: Delayed Administration of Oral Penicillin as Prophylaxis for Gonorrhea, read before the Annual Scientific Session of American Venereal Disease Association, Washington, D. C., April 8, 1949.

The degree to which this generally uncooperative group of subjects accepted penicillin "prophylaxis" and the demonstrated efficacy of the procedure indicate its possible feasibility for the control of gonorrhea in the military forces. Were the penicillin tablets generally available, there is no reason to doubt that it would be as effective also for those in the civilian population who elected to use it.

2. *Complications.*—There are at least four complications which might attend the repeated peroral use of penicillin for the prevention of gonorrhea. In this study, admittedly small in scope and limited as to the number and type of personnel, we have seen no evidence that any of these complications occurs with such frequency as to contraindicate the peroral use of penicillin for the prevention of gonorrhea.

(*a*) There was no evidence of sensitization to the drug, or any other toxic manifestation, when 100,000 unit tablets were taken by an average of approximately 150 men over a period of 16 weeks at an average frequency of 1.1 times weekly, and when approximately 85 of these subjects continued with 250,000 unit tablets over an additional period of 24 weeks at approximately the same frequency. It is to be noted that there were many persons in this group who averaged more than 3 tablets weekly over those entire periods, without evidence of sensitization.

There is, however, good reason to believe that the ingestion of 250,000 unit tablets as often as daily over a period of weeks would in some cases cause sensitization to the drug. One such case was observed in the course of the present study in a group of 7 persons who received daily doses of 250,000 units over a period of weeks in order to follow the effect of such regular daily intake on the bacterial flora of the mouth and intestine.[8] The proportion of persons so affected, the severity and duration of the complication and the permanence of the sensitization are perhaps of lesser importance in relation to the prevention of gonorrhea (in which the penicillin would be taken only intermittently) than they are in relation to the possible use of penicillin for the prevention of other infections (cf. section 3).

(*b*) All the subjects in whom gonorrhea developed were cured with the administration of penicillin in therapeutic doses. There has been no indication of penicillin-fast strains of gonococci developing in consequence of the intermittent ingestion of penicillin tablets by men repeatedly exposed to infection.

(*c*) There has as yet been no demonstrated instance of the suppression or retardation of syphilitic infection caused by the intermittent intake of penicillin tablets. Four cases of syphilis were discovered in the subject population in the course of this study, all detected by serologic test, and without history of a chancre or rash. However, of these 4 cases, 2 were in control subjects who had received no penicillin. The third subject did not have a serologic test when he first reported to the station (April 27, 1948), remained at the station for only a month and was discovered to have a positive serologic reaction four months later. There is thus reason to suspect either the presence of latent syphilis at the time of his arrival or that he contracted syphilis in the interval between May 28 and September 23. The last subject was seronegative Jan. 26, 1948, and was discovered to have a positive reaction on April 16. Although nominally in the experimental group during this period, he had consistently refused penicillin, had had gonorrhea twice and received only a single tablet of penicillin in the entire three month period.

(*d*) The effect of the intermittent ingestion of a single 250,000 unit tablet of penicillin on the flora of the mouth and intestine remains to be determined.[8]

3. *General Considerations.*—The results here reported in the prevention of gonococcic infection bear out the general thesis [1c] that infections suscepible to treatment with penicillin may be successfully aborted during the incubation period by relatively small doses of penicillin. Thus, it may be possible to terminate epidemic outbreaks of such infections by the daily peroral administration of penicillin over a limited period of time to the entire susceptible and exposed population.

The early use of penicillin has been successfully applied to the prevention of syphilis.[9] In the contacts of cases known early and infectious disease, a single injection of 600,000 units of penicillin in oil and wax, administered weeks after the original exposure but before the development of serologic or clinical evidence of infection, decidedly reduced the proportion who subsequently had syphilitic infection. It is a reasonable expectation that procaine-penicillin in oil (with aluminum monostearate) would be even more effective, particularly if administered within a few days after exposure.

## SUMMARY

A single tablet of penicillin, taken by mouth as the men returned from shore leave, and within an average of 2 hours after possible exposure, materially reduced the incidence of gonorrhea in a group of military personnel.

1. In a control group of 176 to 195 men receiving a placebo tablet which contained no penicillin, there were 43 cases over a period of 24 weeks in a total of 3,616 liberties (508 cases per thousand men per year, and 11.9 per thousand liberties).

2. In the experimental group, consisting of 151 to 213 men who received a single 100,000 unit tablet, there were 5 cases in 3,218 liberties (1.8 per thousand liberties, and 105 per thousand men per year). In 3 of these 5 cases there was reason to doubt that the penicillin had been received.

3. When the size of the tablet was subsequently increased to 250,000 units, there was 1 questionable case over an 8 week period in an experimental group of 87 to 141 men with 569 liberties. When the penicillin was then made available to the entire station on a voluntary basis, so that it was taken only by those who had actually been exposed, there was again 1 questionable case in 1,454 liberties followed by penicillin prophylaxis. From the previous control experience one would have anticipated at least 20 cases in these 2 groups of 2,023 liberties.

4. In the dosages and under the conditions here used there were no toxic complications to the intermittent ingestion of single penicillin tablets, no clearcut instance of suppressed syphilitic infection and no indication of the development of penicillin-fast strains of gonococci.

The implications of these observations with respect to the prophylactic use of penicillin in other infections are discussed in the text.

---

[8] Although strains highly susceptible to penicillin disappeared with this regimen, there was no emergence of new, resistant strains (Romansky, M. J.: Personal communication to the authors).

# HEADACHE ASSOCIATED WITH PATHOLOGIC CHANGES IN CERVICAL PART OF SPINE

A. IZARD JOSEY, M.D
Columbia. S. C.

Headache is a symptom suffered at some time by almost 100 per cent of mankind and is the presenting complaint of a high percentage of patients seeking help from a physician. As knowledge of the multitudinous factors involved in the production of headaches has become more extensive the physician has been enabled to furnish more relief for the symptoms. Fortunately most headaches are infrequent and transient and respond to rest or simple analgesics. The more frequent and protracted headaches offer a challenge to the diagnostic and therapeutic ability of the physician, but too frequently relief for the patient is not obtained. Doctors have little knowledge of the actual mechanism of the production of headache, and most thinking in the matter is based on relatively few experimental or pathologic observations and a multiplicity of deductions, some of which are contradictory.

Within the past fifteen or so years the greatest amount of interest has evolved in the various headaches thought to be caused by vascular disturbances in or about the cranium. The works of Penfield,[1] Pickering,[2] McNaughton[3] and Wolff[4] and their co-workers have established the areas of cranial sensitivity as being principally the extracranial arteries of the scalp, the arteries of the meninges and the large venous sinuses and the meningeal structures closely adjacent to these vessels. In addition, these investigators have demonstrated that pain produced in the head anterior to a vertical line bisecting the ears superficially and on or above the tentorium cerebrii is transmitted through the fifth cranial nerve; pain posterior to the ears and below the tentorium cerebrii is carried by the ninth and tenth cranial and the upper three cervical nerves. This explanation fails to account for certain headache phenomena, particularly with the headaches associated with pathologic changes in the cervical part of the spine.

The purpose of this communication is to describe a group of cases in which headaches were associated with a symptom complex and physical observations of a similar nature and the common factor of the roentgenographic demonstration of the loss of the normal lordotic curvature of the cervical part of the spine. Some simple historical points and physical signs will be discussed. It will be shown that demonstrable arthritis of the cervical part of the spine is not necessarily present. This symptom complex is not a new one, but it is one which I am sure is frequently overlooked. Too often the patient is sent off on a round of investigations of eyes, sinuses and teeth, and then all too often the diagnosis is neuralgia, atypical migraine, chronic sinusitis, constipation or psychoneurosis.

## REPORTS IN THE LITERATURE

Pathologic change in the cervical region as a cause of headaches has been the subject of medical writings for many years. Telling[5] in 1911 referred to rheumatic or indurative headache and related it to "fibrositis" in the posterior cervical region. Patrick[6] in 1918 gave a good clinical description of headache which, originating in the cervical region, radiated upward and to the frontal regions. He did not believe that the headache was related to fibrositic nodules in the neck, but rather to focal infection, and noted exacerbations in relation to exertion, rotation of neck and coughing. Gunther and Kerr[7] in 1929 described 8 cases of headache, principally occipital in location but at times with temporal radiation, among 30 cases of arthritis of the spine with what they called a "radicular syndrome." Bisgard[8] in 1932 reported 31 patients with roentgenographically demonstrable arthritis of the cervical part of the spine who had occipital headaches, who obtained some relief by supporting the head with the hand, by lying down or with heat. In 1937 Holbrook[9] presented a plea for more consideration of arthritis of the first three cervical vertebrae as a cause of headache. The type of headache he described was principally occipital in location, but at times there was temporofrontal radiation, was often protracted for months, although variable in degree, and was associated with roentgenologic evidence of hypertrophic arthritis of the upper cervical part of the spine. He used heat and massage and immobilization of the neck but found therapy rather unsatisfactory. Hartsock[10] in 1942, in describing prolonged headache due to cervical arthritis, said that the symptom complex is characteristic, with pain beginning in cervical muscles radiating upward to occiput and forward to temporal regions. In 1942 Kelly[11] reported on a group of 40 patients with headache of various causes, "indurative," "fibrositic," "post-traumatic" and "postmeningeal," who had both occipital and frontal localization temporarily relieved by injections of procaine hydrochloride into localized areas in suboccipital regions. None of these authors except Kelly related the headaches described to trauma. In 1944 Jones and Brown[12] related the headache of "post-traumatic head syndrome" to some type of pathologic change in the upper cervical part of the spine but did not present roentgenologic evidence. These latter two authors used injections of procaine hydrochloride in the upper cervical region with some relief of symptoms. Davis[13] in 1945, in a study of injuries of the cervical part of the spine, pointed out that symptoms, which may include headache, might develop from relatively minor trauma. Such symptoms may appear only after months or years, and the original injury may be overlooked in the patient's casual memory. After a roentgenographic study of a series of normal and post-traumatic cervical spines, he stated that the loss of the normal convexity of the cervical part of the spine always indicates post-traumatic derangement of the posterior intervertebral joints. This change is not generally recognized, and he stated that he did not recognize this abnormality prior to 1936. This loss of the normal curvature of the cervical part of the spine without roentgenographic evidence of generalized arthritis has been pointed out by those authors[14] interested in ruptured disks of the lower cervical region. Little[15] in 1946 reported his experiences in the management of a group of patients with chronic or recurrent headaches who had had various diagnoses, such as, postconcussion syndrome, atypical trigeminal neuralgia, migraine and hysteria, and a high percentage of whom showed roentgenographically a loss of the normal cervical lordosis. He described 3 such patients, only 1 of whom had any known history of trauma. He tried various therapeutic measures and found that head traction, though not highly successful, produced more relief than other measures. Crutchfield[16] used traction with tongs fixed in the skull in a group of cases in which the diagnosis was what is considered occipital neuralgia. No changes in alinement of the cervical part of the spine were noted in his cases, but the results, as far as relief of occipital pain was concerned, were encouraging.

## CLINICAL EXPERIENCE

In the past two years a group of 20 patients with the presenting symptom of headache of a particular variety were seen in my practice. Although not presenting a clearcut symptom complex, the history and physical observations presented many features of a similar nature and the roentgenogram was always characteristic. A history of trauma was usually not obtained except on direct and insistent questioning and often was of such slight degree, or so far in the past, that the patient was not impressed with its relationship to headache. There was usually, but not always, a history of attacks of soreness and stiffness or "cricks" in the neck either preceding or in association with the headaches. The headaches were frequent, almost daily, and usually prolonged and recurrent for weeks or years. Most often beginning in the occipital region with radiation to the frontal or supraorbital region, the headaches were steady and varied from a mild ache to intense pain. The frontal pain was unilateral or bilateral. At times the frontal headache was so predominant that only after direct questioning was any painful symptom referred to the occipital region or the neck. Position of the head and neck appeared to be a definite factor. Headache frequently had its onset while the patient was in bed and in early morning. The position of the head at work, any exertion which placed a strain on the neck and driving a car were often precipitating factors. In some cases the head was held in an obviously abnormal manner, but this was never extreme. Manipulation of the neck usually revealed some resistance to extreme lateral motion, but there was no obvious spasm of the superficial musculature. In practically all cases, firm pressure with the examiner's thumb just lateral to the body of the second cervical vertebra produced pain locally and also a radiating pain which was described as shooting through the head to the frontal or supraorbital region. When the symptoms of headache were bifrontal this phenomenon could often be produced on both sides. Such pressure would almost always reproduce the frontal headache complained of, but it would not be protracted. If the patient was suffering from headaches during the course of the examination, traction simply with the examiner's hands on the head in an upward direction almost always produced temporary relief. Nausea of slight degree was present only if the headache was particularly severe. There was no vomiting. A roentgenogram of the cervical part of the spine in each case invariably revealed an abnormal loss of normal lordotic curvature. In most instances roentgen exposures were made in three lateral positions: (1) head held comfortably erect with the eyes fixed on a spot level with the eyes, (2) in extreme flexion and (3) in extreme extension. The roentgenograms of the normally erect position furnished the easiest demonstrable features. In only 2 cases was evidence of hypertrophic arthritis seen, and this was not of extensive degree.

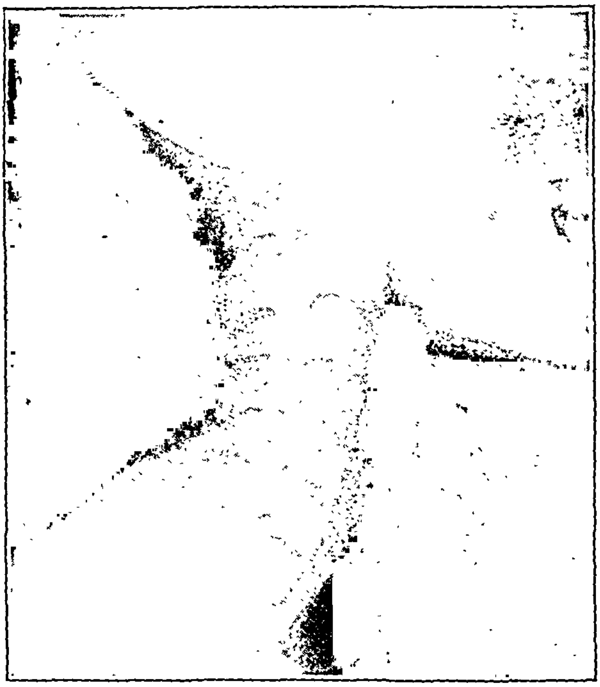

Fig. 1.—Lateral roentgenogram of a normal cervical part of the spine demonstrating the smooth lordotic curvature.

All of the patients described underwent a complete general physical investigation with routine examinations of urine and blood. Special examinations for the usually common causes of headache were carried out where there was any indication. A number of the patients had refractive errors but were wearing suitable lenses, so that eye strain was not considered a factor. None had sinus disease. Hypertension and renal disease were absent in all cases. The psychic element was evaluated in all cases and not considered to be a factor. An allergic diathesis was present in 2 cases but had been controlled by diet and antihistamine drugs prior to the onset of the severe headache in 1 case and could not be considered a factor in either. All cases have been followed long enough to rule out presumably the presence of an intracranial neoplasm. Of the 20, 6 illustrative cases are briefly reported. They were chosen from the group to demonstrate the main features of the syndrome and the variables seen in symptoms, physical and roentgenographic observations and response to therapy.

## REPORT OF CASES

Case 1.—E. D., a woman aged 40, while attempting to enter a slowly moving car, was thrown to the floor of the car on April 5, 1947. She did not appear to be injured at the time and had no specific complaints. One week later an aching pain developed in the posterior cervical region and a sharp pain in the right supraorbital area. There was limitation of extreme motions of the neck. Pressure of the thumb to the right of the second cervical body produced, in addition to local discomfort, a sharp supraorbital pain similar to the spontaneous headache. A roentgenogram of the cervical part of the spine on April 25 showed a loss of normal lordotic curve with a straight alinement from the first to the seventh cervical segment. The cervical and supraorbital pain persisted unremittingly for three weeks, during which time she received local physical therapy and wore a cervical collar constantly. There was some improvement after this, but headaches would reappear after she lay down at night and also on any excess exertion. Driving an automobile, with the necessary frequent movements of the head, would always produce an aching sensation in the neck and the right supraorbital headache. These symptoms were frequent for about three months and necessitated the use of a cervical collar at intervals. During this period the patient would frequently awaken at night with headache and would apply the cervical collar for relief. Gradually the aching in the neck and headaches became less frequent, but even eighteen months after the original injury the exertion of lifting any heavy object or driving an automobile in traffic would be followed by the same symptoms, which could be controlled by administration of an analgesic. A lateral roentgenogram of the cervical part of the spine on Sept. 14, 1948, showed some improvement in comparison with the original roentgenogram in that there was a slight curvature seen, but far from the normal lordotic curvature.

Case 2.—J. C., a man aged 49, seen on May 3, 1948, had suffered with attacks of headache for an undetermined number of years. The greatest discomfort was a dull to sharp ache across the frontal region, with more localization over the left eye and with some radiation to the left occipital region. These headaches appeared at irregular intervals of one to three months and would persist for two to fourteen days. There was no particular time of day for their appearance, but when present they were constant. He was unable to determine any specific precipitating factor, but excess exertion was thought to be contributory. He sought an explanation from many physicians, but he was led to believe that his headaches were caused by constipation or sinusitis. Only after close search of his past history was it disclosed that he had received a head injury in 1918 and had been unconscious for eight hours. He also had fallen out of a tree at the age of 10 years. Examination showed no real limitation of movements of the neck. Pressure just to the left of the second cervical body produced slight but definite radiation of pain through the head to the left supraorbital region. During an attack of headache the application of head halter traction for a few minutes gave prompt temporary relief of the head pain. A roentgenogram of the cervical part of the spine showed an abnormally straight alinement from the first to the seventh cervical segment without any evidence of arthritic changes. He was instructed to use head halter traction at home three or four times a day for fifteen minute periods. After three weeks he did not suffer any further headaches. He was then instructed to use traction at the onset of any headache. When last interviewed, on October 15, he stated that he had had only occasional mild headache in the frontal region, occurring sometimes at night and again when he was fatigued. Coughing and sneezing also would cause some frontal pain. In general he had shown remarkable improvement and had not had to use traction for several months.

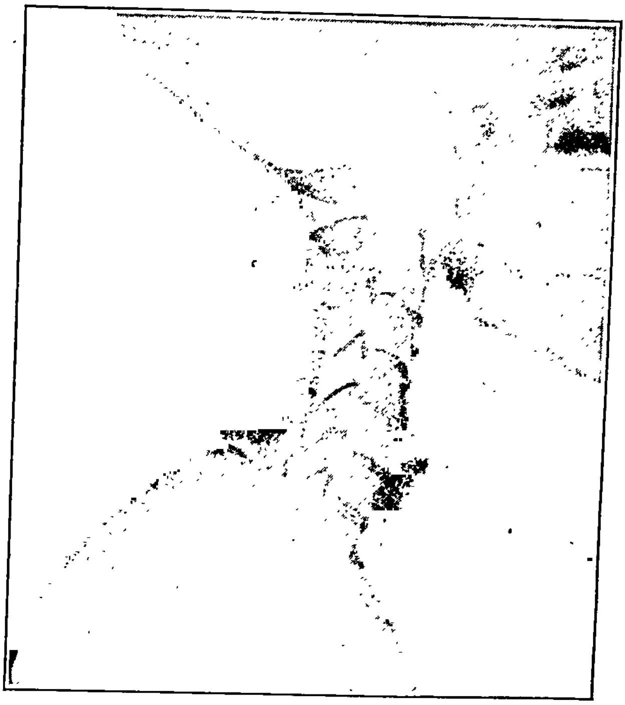

Fig. 3. (case 1).—Lateral roentgenogram taken Sept. 14, 1948 showing slight return of posterior curvature, but the second through the fifth cervical bodies have a straight alinement.

CASE 3.—Y. W. H., a male draftsman, seen Nov. 1, 1946, had frequent headaches as far back as he could remember. Pain was bifrontal, beginning over either eye and spreading at times radiating to the occipital region. Attacks would occur almost daily for several months with some periods of remission for several weeks. Usually onset of the headache would be early in the morning with some relief after arising and use of analgesics, but the onset at times would follow physical exertion or driving a car for long periods of time. In addition, he had suffered with attacks of "cricks" in the neck for a number of years, not necessarily related to headaches. There was limitation of right lateral motion of the neck. Pressure to the right of the second cervical body produced sharp right supraorbital pain which seemed to radiate through the head. A roentgenogram on November 1 disclosed a loss of the normal curvature with slight anterior angulation at the fourth cervical segment. He was instructed to use head halter traction for twenty minutes twice daily and to sleep without a pillow. This gave some relief of symptoms for a time, particularly the neck pains, but the symptoms of headache persisted with little abatement. Various drugs were tried, including nicotinic acid, ergotamine tartrate (gynergen®) and tripelennamine hydrochloride (pyribenzamine® hydrochloride). None of these had any effect. He obtained some relief with acetylsalicylic acid with occasionally some codeine. Although the headaches were discomforting they were not incapacitating, and he did not wish to try any further or more drastic therapeutic measures. A roentgenogram of the cervical part of the spine on Sept. 15, 1948, showed no change from the original roentgenogram.

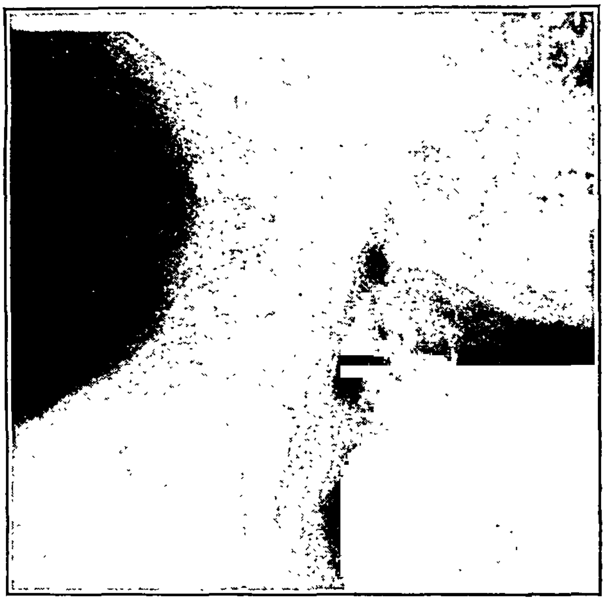

Fig. 4. (case 2).—Lateral roentgenogram showing straightening of the bodies of the entire cervical portion of the spine.

CASE 4.—A. C., a woman aged 38 years, a typist, was first seen Dec. 15, 1947. At 6 a. m., December 13, severe throbbing pain occurred in the right occipital region, which disappeared in half an hour. About 1 p. m. the same day severe pain developed in the right occipital area which radiated to the right parietal and then through to the right supraorbital region, lasting two hours. Again on December 14, about 8 a. m., severe right occipital and right frontal pain appeared in association with aching in the right upper cervical region which persisted to the time of reporting to my office the next day. She admitted to an injury to her coccyx at the age of 13, but only after close questioning was the history of a recent fall elicited. On December 6 she fell a short distance on stone steps, striking her chin. She was dazed for a few minutes but had no other immediate complaints. In addition, she had had infrequent attacks of "stiff neck" for about ten years. There was no limitation of motion of the neck. Firm pressure just to the right of the second cervical body produced a sharp pain in the right frontal region. A roentgenogram revealed a fusion of the fifth and sixth cervical bodies, thought to be congenital, and a straightening of the bodies of the first through the sixth cervical vertebrae. Traction applied in the office gave temporary relief of the headaches. She was instructed to use head halter traction at home for fifteen minutes three times daily and to wear a cervical collar at night. She obtained considerable relief from these measures, and the persistent headache disappeared after sixteen days. The headaches occurred at frequent intervals for the next ten weeks, and there was considerable increase associated with coughing and sneez-

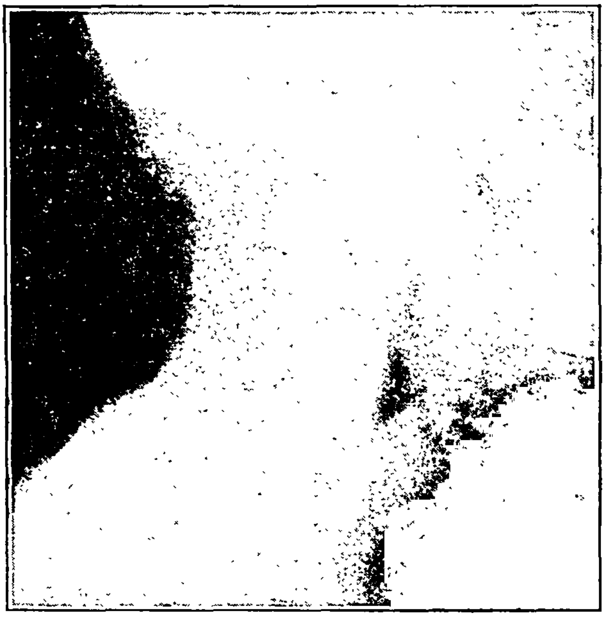

Fig. 5. (case 3).—Lateral roentgenogram taken Sept. 15, 1948. There is total loss of lordotic curvature.

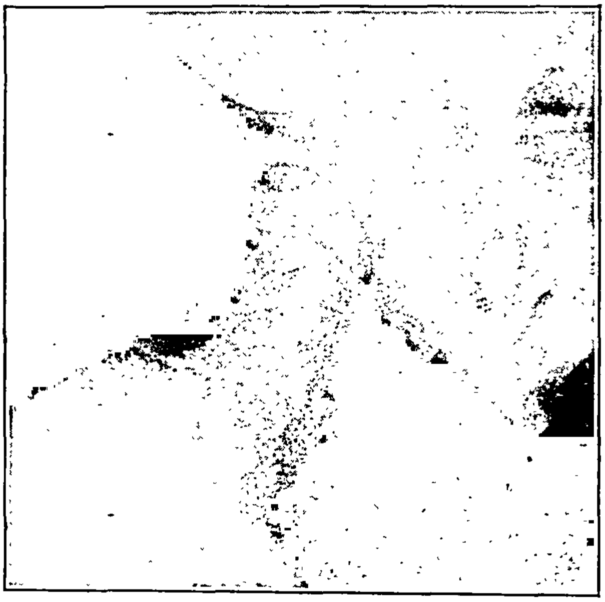

Fig. 6. (case 5).—Lateral roentgenogram taken Sept. 15, 1948, showing loss of normal curvature from the first through the fourth cervical segments. Slight arthritic changes are present.

ing during an attack of coryza during the week of Jan. 14-21, 1948. Up to the time of reporting, Oct. 15, 1948, she occasionally had a moderate headache if she was overfatigued or following prolonged work at a desk with her head flexed. This headache responded to rest and administration of an analgesic. A roentgenogram taken September 27 showed a slight, but far from normal, lordotic curvature of the cervical part of the spine.

Case 5.—H. H., a housewife aged 50, had had headaches almost daily for over twenty-five years. Pain was in the upper, posterior cervical, occipital and bifrontal regions. Occurring on her awakening in the morning, they were usually less noticeable after she became active, but were always made worse with excess physical exertion. At rare intervals there had been some pains in the right shoulder region and right upper arm. She had sought relief from many physicians. In addition, she had had hay fever for many years, but with some relief by the attention of an allergist in the previous several years, without any effect on the course of the headache. At age 5, she had fallen from a second story window and was unconscious for several hours. She was first examined May 9, 1946. The neck was held rather stiffly, and there was definite limitation of flexion. Pressure laterally to the left of the second and third cervical bodies produced occipital and left frontal headache. A roentgenogram showed loss of normal curvature from the first to the fourth cervical segments, and slight arthritic changes were seen. Traction with a head halter was followed by temporary relief of the headache. Use of the head halter at home failed to prevent the daily headaches, and she reverted to the use of the analgesics she had previously used. She continued to have almost daily headaches, and prolonged rest was the only measure which produced any effective relief. A roentgenogram on Sept. 17, 1948, showed no change from the first roentgenogram.

Case 6.—B. H., a male executive, aged 52, seen July 9, 1947, first experienced an aching pain in the left occipital and suboccipital region on July 7, which had been moderate but persistent. At 3:30 a. m., on July 9, he awakened with a severe sharp pain in the left temporofrontal region which lasted about forty-five minutes. Again, about 11:00 a. m., the same symptoms returned and were rather severe when he coughed or turned his head. There was no known injury to the head or neck in the recent or remote past. There was limitation of extreme movements of the neck in all planes. Pressure just left lateral to the second cervical body caused sharp left frontal pain. A roentgenogram taken on July 9, 1948, showed straightening of the entire cervical part of the spine with slight anterior angulations at the fifth body. He was given acetylsalicylic acid and codeine and asked to use the cervical collar at night. After three weeks the headache and neck pain was almost completely relieved and he had suffered only slight return at infrequent intervals. In spite of the abatement of symptoms, a roentgenogram taken September 4 showed no demonstrable change.

## COMMENT

The principal characteristics of this group of patients are occipital pain and frontal pain, frequently related to position of the head and exertion which places a strain on the neck. The headaches may be primarily occipital or frontal, may be unilateral or bilateral. In almost all cases there is associated aching in the posterior cervical region or a history of attacks of "cricks" in the neck. The symptoms are most often intermittent or protracted over months or years, but may be rather transient, as in case 6. Most often a history of trauma to the head or neck could be obtained, but this was either of such mild nature or so far in the past as to be overlooked and not related by the patient to the headaches. Frequently the component of frontal pain could be reproduced by pressure lateral to the second cervical vertebral body. The one common factor in all cases was the roentgenographic finding of a loss of normal cervical lordotic curvature. Demonstrable arthritic changes were seen in only 2 of the cases, and, as this process was observed in the lower cervical region, it was not thought to be contributory to the symptoms. It is of interest to note that 2 patients (cases 1 and 4) showed slight but definite changes in the roentgenogram, with a tendency to return of the normal lordotic curvature after a period during which there was symptomatic improvement. One patient (case 6), whose symptoms were of only short duration, inexplicably showed no change in the alinement of the cervical bodies after fourteen months. The 2 patients whose symptoms were of longest duration (cases 3 and 5), and whose symptoms did not change, showed no demonstrable roentgenographic changes after two and a half and two years, respectively.

The exact nature of the anatomic or physiologic pathologic change cannot be definitely stated. From what is known of the innervation of the fore part of the head and the structures within the cranium above the tentorium by the fifth cranial nerve and the posterior aspect of the head and the subtentorial intracranial structures by the upper three cervical and the ninth and tenth cranial nerves, it is difficult to explain the transmission of the headache through these pathways. It is well known that the sensory nucleus of the fifth cranial nerve extends down the spinal cord to the level of the third cervical segment, but there are no known synapses with the upper cervical sensory nerves. It is difficult satisfactorily to conceive any direct connection of the nucleus playing a direct part in the pain involved in these cases, but such may be possible. Wolff and his co-workers[17] noted transient pain in the neck after prolonged headache from various causes, but that type of mechanism hardly seems likely in this group of cases. Inman and Saunders[18] produced deep and widespread pain in various parts of the human body by various irritants in muscles, fascia and ligaments and described it as "scleratomal distribution." Campbell and Parsons[19] produced pain in the paraorbital area of human beings by injecting a little 6 per cent sodium chloride solution into the occipitoatlantal periarticular tissues, and both occipital and frontal pain by similar injection into the periarticular tissues of the second cervical region. These authors also wrote of "scleratomal distribution" and noted the painful areas to be closely related philogenetically and physiologically. Hadley[20] stated that the normal curvature of the cervical portion of the spine is maintained in the absence of trauma even when arthritis is present, and Davis,[13] as previously noted, called attention to the relationship of trauma to the straight cervical portion of the spine. One is left with the deduction that trauma producing an injury in the nature of a sprain to the paravertebral ligamentous structures is the primary factor in the type of headache described, further evidencing itself in an abnormally straightening of the entire cervical portion of the spine due to reflex

muscle spasm. Arthritis may be a factor late in the condition, but its presence is not necessary for the production of the symptom complex. Most probably the location of the injury is in the upper cervical region, in the first two or three segments, and it is not thought to be a disk lesion, as rupture of the intervertebral disks at this level has not been described. Such may be the case, however. Shoulder pain, arm pain and paresthesia of the arms and fingers were not usually observed in these cases, so that it is assumed that the lesion is not a ruptured disk of the lower cervical region, although the roentgenologic observations are somewhat similar to those of rupture of a lower cervical disk. It differs in that in ruptured cervical disks of the lower cervical region the straightening of the spine is predominantly in that area, while in the cases presented the straightening was either of the entire cervical portion of the spine or in the upper portion.

Treatment in all of these cases has not been exhaustively applied. Some of the patients had learned to put up with their symptoms, or had obtained some measure of relief from self-prescribed analgesics and added rest. When the symptoms were particularly severe, lying supine with a pillow under the shoulders, the use of a cervical collar bandage or head halter traction produced temporary, and in some cases semipermanent, relief. In cases 2 and 4, in which symptoms were rather severe, the use of head traction was definitely followed by satisfactory improvement. In 4 of the cases the symptoms subsided to the point where practically no therapy was needed. In 2 cases the therapy applied failed to effect any change. Ergotamine tartrate, nicotinic acid and antihistaminic drugs were used in 1 case with protracted symptoms without relief. Procaine hydrochloride injections about the bodies of the upper cervical portion of the spine was not attempted except in 1 case, and no permanent relief was obtained.

### SUMMARY

A group of patients is reported with frontal and occipital headaches, usually aching in the neck and always with a loss of the normal lordotic curvature of the cervical portion of the spine as seen roentgenographically. The cause of this headache is in all probability an injury in the nature of a sprain to the upper cervical part of the spine. The transmission of the pain to the frontal region is probably mediated through a "scleratomal" distribution or may in some way be related to the cervical portion of the nucleus of the fifth cranial nerve. Treatment is mainly directed toward simple immobilization of the head and head traction.

**Brain Surgery.**—The brain has been called the Mount Everest of surgeons, and it is not surprising, therefore, that surgeons did not tackle brain tumours until 1880, when the surgery of most other parts of the body was well under way. The most important pioneer work in brain surgery was done by two men in Britain, William Macewen, of Glasgow, and Victor Horsley, of London. After thirty years of hard work on the part of these and other workers the mortality from operations for brain tumour was still 50%. In the next fifteen years, and especially after the first world war, largely owing to the work of Cushing in America, the mortality was reduced to 15%; and now it is down to 10% and should go lower.—Sir Hugh Cairns, Nuffield Professor of Surgery, Oxford; *The Australian and New Zealand Journal of Surgery,* July 1948.

## TREATMENT OF PARAPLEGIA RESULTING FROM TRAUMA TO THE SPINAL CORD

L. W. FREEMAN, M.D., Ph.D.
Indianapolis

The essentials in the care of the patient suffering from a paralysis of the legs resulting from injury to the spinal cord consist of the prompt application of the following points:

1. Rotation or flexion of the spine should be studiously avoided or the spinal cord may be severed.
2. The deformity of the spine should be promptly reduced by traction or hyperextension or both.
3. The patient must be turned every two hours at least.
4. Proper care of the bladder includes:
    (*a*) Avoidance of distention or continuous contraction.
    (*b*) Encouragement of the development of an automatic bladder.
    (*c*) Avoidance of urinary sepsis, or prompt treatment if it occurs.
    (*d*) Prevention of urinary calculi by exercising upper extremities in bed and by early ambulation.
5. Proper care of the skin
    (*a*) Avoid prolonged pressure; turn frequently.
    (*b*) The bed should be clean, dry, smooth and flat.
    (*c*) Maintain adequate protein intake.
    (*d*) Large decubitus ulcers should be repaired surgically.
6. Care of the bowels
    (*a*) Relieve intestinal distention and constipation promptly, with:
        (1) Pituitrin or neostigmine.
        (2) Enemas and rectal tube.
    (*b*) Watch for and remove fecal impactions promptly.
    (*c*) Develop proper bowel habits.
7. Watch for, prevent and, if necessary, promptly treat anemia, hypoproteinemia and vitamin deficiencies.
8. Constantly be on the alert for complicating emotional reactions and help the patient to accept the reality of his difficulty.

The bases on which the treatment prescribed have been established are not necessarily original. In many instances the course outlined merely represents one of several which have been advocated, but the one preferred by the committee. The genesis of what is considered to be the ideal method of treatment could easily be followed, in a temporal sense, over the course of several years during which more than 720 paraplegic patients were under my care. No phase of the entire program failed to reflect my opinions, but the frequency with which the superior knowledge of others swayed my opinions needs little emphasis.

It might be well to reiterate the "Munro doctrine,"[1] a profession of faith that may be unjustified in an

absolute sense, but certainly cannot be assailed as a goal toward which to strive. It states, "If he has been properly treated, every patient with a spinal-cord or cauda equina injury who is intelligent and cooperative and has the use of the shoulder, arm, and hand muscles can be made ambulatory; can have such control of the bladder and bowels as to sleep through the night without either getting up or wetting himself; can carry out ordinary activities throughout the day without soiling himself with feces or having to evacuate his bladder oftener than once every three hours; can lead a normal social life, and within the limits of his intellectual capacity, can earn a satisfactory living." [1c] No such goal was imagined in the early phases of experience, but as general medical knowledge was given specific application, it became obvious that some such goal was attainable. For this reason, the later papers of Munro [1c, d] served to cement these beliefs.

For reference, the writings of many neurologists, neurosurgeons, and urologists may be consulted.[2] That many of the methods prescribed are still the subject of bitter controversy cannot be denied. Wherever such differences exist, reference will be made to pertinent papers.

### TRANSPORTATION

Patients with injury to the cervical spinal cord (quadriplegia) should be transported face up [3] or face down.[1e] The arguments for transportation in the face-down position include the avoidance of oral intake of fluids during transportation and the elimination of possible aspiration of vomitus. These factors appear to be less important than other considerations in the uncomplicated case. Thus, it seems apparent that transportation in the face-up position is more favorable, for it produces less strain on an already embarrassed respiration. Furthermore, the distress of the patient is lessened considerably, traction can be applied more easily and measures aimed at prevention of turning of the head are more advantageously applicable. It seems somewhat useless to argue the merits of these systems, since it is all too frequently obvious that the initial attendants to the injured person are almost invariably uninformed. Were an informed person in attendance, he would in all likelihood regulate the position for transportation by the availability of help, the vehicular accommodations and the condition of the patient. It is likely that the average patient is best handled in the face-up position, with all precautions being taken to prevent flexion and rotation of the head with respect to the rest of the body. In the face-down position, it is difficult to insure a proper airway without turning the head to the side—obviously a contraindicated measure. A rolled garment in the nape of the neck or beneath the shoulders will insure extension. Traction on the head from the chin or heavy rolls at each side of the head will prevent rotation. Ambulances could carry a brace described by Dingman.[4] This sectional brace is easily applied with a minimum of moving and offers safety in transportation of the patient by providing both immobilization and traction at the same time. Should an effort be made to correct obvious deformities at the place where the injury has occurred before the patient is transported? Certainly closed manipulations in the face of embarrassment of the cervical cord are hazardous under the best of conditions, and the likelihood of aggravation of the effects of the injury is enhanced by such procedures. On the other hand, the structures in the cervical region are mobile and subject to easy manipulation.[2b] Again, it is often found that the initial attendants will have already manipulated the head. Laymen often speak of cases in which manipulation appears to have resulted in life saving. The informed attendant would probably do no more than apply steady traction to the head, awaiting roentgenographic demonstration of the bony lesion.

For injury to the vertebral column in the thoracic region, transportation in the face-down position is accepted almost universally. The injury in this region usually occurs after a sharp flexion insult, and extension tends to reduce or minimize the deformity. Traction is of little use because of the splinting of the thoracic spine by the chest.

Transportation in the face-down position is likewise accepted for the patient with injury to the lumbar vertebral bodies or to the lumbar cord for the same reasons previously cited. Here, however, traction to the legs may be of some benefit.

### ROUTINE ON ADMISSION TO THE HOSPITAL

Injury to the spinal cord should be considered a surgical emergency. As such, certain principles must be held in mind. First, the patient should not be moved any more than is absolutely necessary. Second, if surgical procedures are indicated, there is no basis for one's considering a patient as requiring routine care on admission and emergency care several days later. The term "spinal shock" has been the subject of misinterpretation and is actually a misnomer.[5] Barring other injuries that result in surgical shock, the patient with acute injury to the spinal cord suffers no disability other than loss of all voluntary and reflex activities below the point of his lesion. A lowered blood pressure is usual, but this alone does not justify the diagnosis of surgical shock.[6] It is possible that operative intervention will be helpful in the early hours,[7] provided that such intervention is indicated; otherwise, one can await the results of conservative treatment.

The first step on admission is physical examination of the patient on the stretcher. Presuming that the only lesion suffered has been to the spinal cord and its surrounding structures, a neurologic examination should be made. Actually, one need not be a skilled neurologist to determine the site of injury to the spinal cord. A pin, the finger nail or any sharp object drawn from the legs upward will show the level of the sensory loss produced by the lesion. The testing should not be carried out from above downward, as the level thus demonstrated is apt to be inaccurate. Figure 1 demonstrates the relationships between the spinal cord, the dermatome levels as projected on the skin and some familiar body landmarks. Anesthetic levels between the nipple line (fourth dorsal) and the inguinal ligaments (first lumbar) offer little difficulty of determination. It is only in the arms and the legs that confusion arises for the neophyte. As seen in figure 1, even these areas offer none too great an obstacle. A more complete examination would include testing of such functions as position sense and vibratory sense (dorsal columns), touch and localization (anterior spinothalamic tracts) and pain, hot, and cold (anterolateral spinothalamic tracts) as well as all movements and reflexes.

When one has established the probable site of the lesion in the spinal cord, this particular region of the cord is related to the surrounding bony architecture. In general, the lower the lesion is in the spinal cord or spinal nerves, the greater is the discrepancy between the dermatome and vertebral levels. The probable site of the bony lesion is then used as the centering point for roentgenograms of the vertebral column. Verification is sometimes obtained by the presence of an actual deformity of the back that can be detected by palpation. Anteroposterior and lateral roentgenograms are usually sufficient, although oblique roentgenograms may often be desirable. These should be taken on the original admission stretcher, if possible, and without appreciable movement of the patient. It is highly desirable that the responsible physician be in attendance throughout.

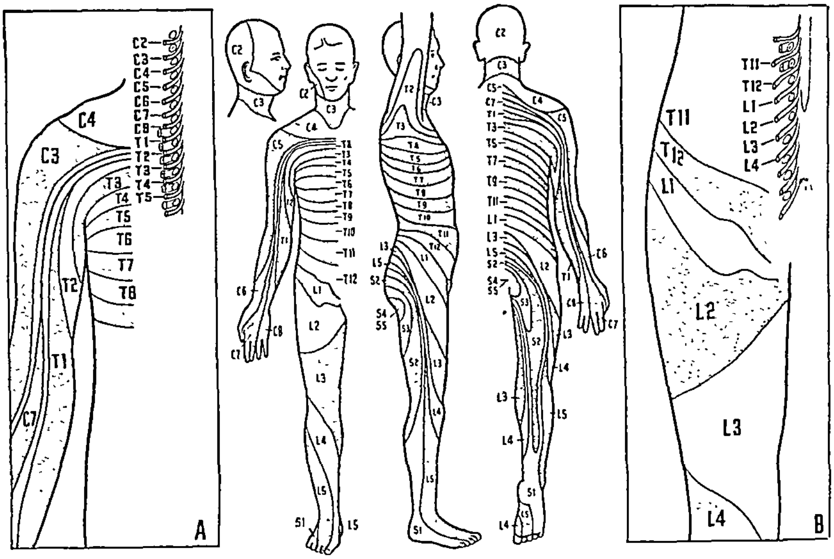

Fig. 1.—Dermatome pattern (after Bailey), with insert *A* showing the disparity between the level of root origin from the cord in the cervicodorsal region and the dermatomes supplied. Insert *B* shows the same relation for the lumbosacral area.

While one is awaiting the development of the roentgenographic plates, a no. 16 French Foley (or, if this type is unavailable, a soft catheter of the same size or smaller) should be inserted under aseptic conditions. The amount of urine obtained must be recorded, for if it exceeds 800 cc. it is likely that the bladder will not show the proper rate of development of reflex activity or return to normalcy that otherwise can be expected in almost every case. This urine should be cultured to serve as a background for subsequent bacteriologic studies and should be examined microscopically. If there is evidence of blood in the urine, pelvic roentgenograms are mandatory and the entire urinary tract may need extensive investigation.

From the roentgenographic department the patient is brought either to his room or to the operating pavilion, still on his admission stretcher. Lumbar puncture with careful manometric studies can now be carried out. Actually, it seems largely academic to discuss the pros and cons of the value of lumbar puncture. The presence of a complete spinal fluid block would indicate a complete occlusion of the subarachnoid space. Anything less than this, even with the so-called quantitative Queckenstedt sign, simply implies an occlusion of the subarachnoid space lying somewhere between a complete blockage and an opening the size of the needle used.[8] Without denying the usefulness of lumbar puncture in gradually developing paraplegia due to tumors and the like, I consider unlikely that advocates of careful manometric examination in patients with acute injury to the spinal cord will ever be able to present statistically significant figures to justify their insistence on this measure as routine. Certainly, in the presence of suspected concomitant cerebral injury, the manometrics would be eliminated. Lumbar puncture by itself, with measurement of the initial pressure, has no contraindication other than the required turning of the patient. On the positive side, one can determine the presence or absence of complete blockage and the presence or absence of blood. The observation of a complete block means little, and the observation of no block means little more. Specific circumstances can easily be cited where either of these observations might be of importance, but their likelihood of occurrence must be afforded statistical insignificance. By and large, the observations on lumbar puncture should receive minor consideration.

On examining the roentgenograms, one must keep certain points in mind. Vertebrae do not slip by each other without injury at least to the ligamentous and cartilaginous structures. In addition, it is infrequent that fracture of the articular facets does not occur. Frequently these fractures take place through the lamina. It has been my experience that the roentgenographic interpretation of the status of the lamina is unreliable. This is largely a result of the inability to secure proper visualization because of the interference of surrounding structures such as the vertebral bodies. Only rarely has it been possible to diagnose even serious laminar fractures prior to laminectomy.

In which cases should open operative procedures be carried out? Agreement is general that all incomplete lesions showing a gradual progression of disability should be explored,[9] in the belief that subdural hemorrhage may be found and arrested or that some other progressive lesion may be controlled. As an academic point, this is open to question. The number of reported cases is extremely small.[10] Also, the serpentine hemorrhages which occur within the substance of the cord are almost impossible to differentiate clinically.[11] However, on the chance that a surgically amenable condition will be found, exploration is advisable. On the opposite side of the picture, when all signs point to a complete transverse lesion most neurosurgeons are inclined to advise conservative treatment, especially when the wound is closed.[12] Most agree that wounds of the cauda equina, whether open or closed, should be considered to be wounds of peripheral nerves and thus amenable to open operation.[13] Some have been enthusiastic about almost routine exploration of all injuries to the spinal cord, especially when a spinal fluid block is present.[14] The policy of the individual neurosurgeon will govern the best method of treatment in a given patient. In the hands of competent neurosurgeons, the mortality rate in laminectomy is extremely low, especially when the hazards of general anesthesia are not included. I have explored most acute lesions, with a gratifying number of patients showing return of useful function and without a single surgical death. If open operative procedures are contemplated, properly typed and matched blood should be on hand for supportive therapy during operation. It is again an academic point to argue that the treatment of blood loss is the avoidance thereof. Even simple surgical procedures are often accompanied with the loss of at least a pint (473 cc.) of blood.[15] In cases of injury of the spinal cord the loss of blood is often not well tolerated.

---

[8] Poppen, J. L., and Hurxthal, L. M.: Normal Cerebrospinal Fluid Dynamics in Spinal Cord Tumor Suspects, J. A. M. A. **103**: 391-393 (Aug. 11) 1934.

[9] (*a*) Oldberg.[2b] (*b*) Pilcher.[3c] (*c*) Poppen and Hurxthal.[8] (*d*) Reports of Committees upon Injuries of the Nervous System: II. Injuries of the Spinal Cord and Cauda Equina, Medical Research Council, Special Report Series, no. 88, London, His Majesty's Stationery Office, 1924, pp. 54-58.

If open operative procedures are not decided on, the course to be followed must be determined. In cervical lesions, traction is mandatory if displacement of vertebrae is present. Even if no dislocation is diagnosed, traction is the most comfortable and safest method of safeguarding against further damage to the injured cord. Halter traction entails certain hazards, such as pressure on the jaws with the possibility of erosion of skin, toothache and restriction of feeding. These hazards are not present with the application of Crutchfield or other types of tongs,[16] but certain points must be remembered in applying these. The first is to avoid placement over the motor areas (straight above the anterior part of the ears) and to determine with certainty that the inner table of the skull is not pierced. If no tongs are available, stainless steel wires threaded between the skull and the dura mater on opposite sides of the longitudinal sinus are a satisfactory substitute. Initial traction should not be enough to give the patient discomfort. Usually 5 to 8 pounds (2 to 4 Kg.) can easily be tolerated. Additional weight, up to 25 or 30 pounds (11 to 14 Kg.), should be added gradually until roentgenographic check-up reveals adequate reduction. In a few cases, it will be found that the facets are locked and will require operation or manipulation.[17] The latter can hardly be sanctioned, despite approval by some surgeons. Neurosurgeons are all too aware of the disastrous aftermath of manipulation of the vertebral canal by osteopaths.[18] The principle of closed reduction of fractures often involves increasing the deformity before the deformity itself can be reduced. With the spinal canal already reduced to a point where the spinal cord is being impinged on, such manipulation may readily result in further neural damage. It is far better to allow the bony lesion to remain as it is than to expose the patient to a dangerous procedure. In figure 2 is seen the reproduction of a roentgenogram of a patient who had almost no disability except for loss of deltoid activity. Not that such an end result should be accepted, but to illustrate an extreme, this case is presented.

L. M., a 33 year old Negro, was injured in an automobile accident, suffering loss of consciousness for five days. It was stated that he had an immediate quadriplegia and was placed in hyperextension without traction for twenty days. With return of consciousness, bladder control was present, but it was two months before bowel control was regained. Within one month after injury, function began to return, followed shortly by the recovery of movement in the hands and arms. When first seen, almost five months after injury, the patient was completely ambulatory, with full control of urination (some urgency), defecation and erectile power. Results of examination were normal except for (1) exaggerated tendon reflexes on the left side; (2) absent abdominal and cremasteric reflexes on the left; (3) slight hypesthesia on entire left side of the body, starting at the sixth cervical dermatome; (4) decided atrophy of the left deltoid and pectoral muscles; (5) moderate atrophy and weakness of the right deltoid muscles, and (6) hyperesthesia of the third to fifth cervical dermatomes on the right and from the second to sixth cervical dermatomes on the left.

If traction is decided on, it still is necessary to determine the probability of benefit from later laminectomy. The factors involved in this decision include (1) locking of facets, (2) recovery at a rate less than could be expected or (3) persistence of a cerebrospinal fluid block. The first point has already been discussed. The second point requires further elaboration. The presence of root symptoms, and their persistence, indicates the likelihood of at least limited improvement by surgical decompression. Since neurologic improvement can be expected within hours after the application of traction, delay of such signs for days has several meanings. First, the lesion may be irreversible and, as such, may be beyond aid. Second, the lesion may be maintaining its status because of surgically amenable deformities, such as protrusion of an intervertebral disk or projection of a bony fragment from a fractured lamina into the spinal canal. How can a decision be reached? Lumbar puncture with careful manometrics may be of benefit. At least some measure of the patency of the subarachnoid space can

be obtained. Usually, any degree of patency is considered to be adequate patency. Lack of patency means encroachment of a severe degree. Is this encroachment too great? There is no way to tell except by exploration. The question then revolves around the possible benefit of laminectomy and the value of the knowledge of the status of the cord versus the hazards of the procedure. This must be an individual decision.

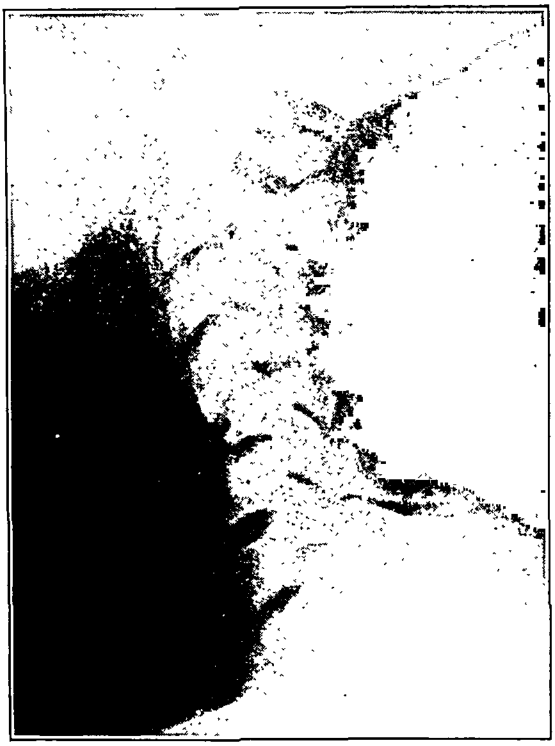

Fig. 2.—Lateral roentgenogram of the cervical part of the spine of L. M., a 33 year old Negro. The fourth cervical vertebra is displaced anteriorly on the fifth, with little or no space left representing the spinal canal. The facets are locked, and the superior articular process of the fifth cervical vertebra has been crushed. The anterior superior edge of the body of the fifth cervical vertebra shows fracture. The early bony bridging between the fourth, fifth and sixth vertebrae may be noted. This roentgenogram was taken five months after injury, when the patient was almost fully recovered.

Assuming that traction is used, the Stryker frame can be used by drilling a hole through the center revolving pin. The usual accessories can be attached to the regular hospital bed. In spite of the presence of traction, the patient must still be turned at one to two hour intervals. Details of nursing care have already been described.[19]

Postoperatively, the patient can be handled most easily on a Stryker frame[20] (fig. 3). If this device is not available, a hair mattress with boards beneath it, a sponge rubber mattress, an air mattress or an innerspring mattress can be utilized. Regardless of the type of support utilized, the patient must be turned at least every two hours, but preferably every hour, night and day. Even the appearance of an area of skin resembling a first degree burn should be studiously avoided. No single feature of care of paraplegic patients will reflect inadequacy of care as readily as the development of decubitus ulcers. This will be discussed more fully. A careful check on intake and output of fluids must be kept. Daily analysis of urine and weekly determinations of hemoglobin, red and white blood cells and serum proteins should be done. In the early stages of care, plain roentgenograms of the abdomen should be taken no less frequently than monthly as a check for calculi in the urinary tract. Fluids should be kept adequate to maintain a urinary output of more than 2,000 cc. daily. The diet should have a high protein, high vitamin and high caloric content. In the face of a falling serum protein level, the following formula will be found to be helpful in obtaining a high protein intake:

| | |
|---|---|
| Powdered skimmed milk | ⅔ cup (315 cc.) |
| Skimmed milk | 1 pint (473 cc.) |
| Egg whites | 6 |
| Sugar | 1 to 2 tablespoons (15 to 30 cc.) |

Flavored to taste and sweetened to desire (after Kleinman[21]).

This formula provides 92 Gm. carbohydrate, 70.5 Gm. protein and 2 Gm. fat for each quart, a caloric content of 665 calories per quart. It should be given as between meal feedings, for it empties from the stomach rapidly. It may be cooled, frozen or warmed as desired.

### CONTINUED CARE

As already indicated, diet and fluids require careful attention. The following phases require specific attention:

1. *Bladder.*—Whenever there is severe damage to the spinal cord or spinal nerve roots in the cauda equina, there is complete flaccid paralysis of the bladder initially. If the rational method of bladder care outlined by Munro[1f] is followed, it may be possible to discard the catheter with the development of automatic action of the bladder as soon as six weeks after injury. Small wonder that the almost routine performance of suprapubic cystotomies by the armed forces

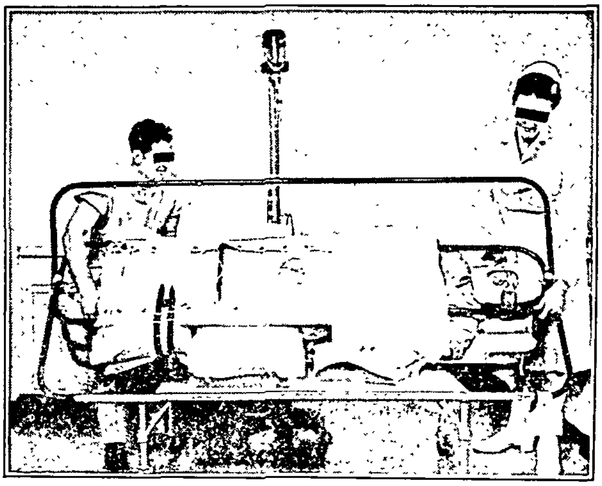

Fig. 3.—A patient being turned on a Stryker frame. The sheet and the broad leg band afford additional security in preventing the patient from falling out if the turning is done too slowly. Pillows are in position before the bottom or top sections of the frame are applied, making lifting unnecessary.

was eyed with wonder by some.[22] Most paraplegi patients do not reach the urologist.[23] Urologists o consider suprapubic cystotomy the ideal met

treatment of the paralyzed bladder.[24] This attitude is based largely on observations from World War I. Neglected patients should have at least temporary suprapubic tubes, but cystotomy cannot be regarded as necessary and, in fact, is usually unnecessary in most paraplegic patients.[1b] Urologists who have had extensive experience with paraplegic patients advocate the rapid abandonment of suprapubic intubation[25] and its replacement largely by the methods outlined by Munro. If nothing more than the following procedure is carried out, many patients with spinal cord injury will have at least an automatic bladder within six weeks: 1. Immediate aseptic catheterization with a no. 16 French Foley catheter with a 5 cc. retention bag. 2. Immediate cystometric examination (conducted as follows [fig. 4]: with the siphon tube clamped off, 50 cc. of fluid are added at a rate of 100 drops per minute and the level of fluid in the cystometric tube is read; another 50 cc. are added and the reading is again taken; this is continued until 400 cc. have been added, the pressure reading has reached 70 cm. of water, or leakage has occurred around the catheter. In the acute stage, the pressure at 400 cc. of fluid will usually be found to be in the range of 5 to 8 cm. of water). 3. The siphon tube is now set at the level at which the fluid was found to rise in the cystometer tube when 400 cc. had been instilled. Cystometric examination of this type should be carried out at least once a day, and the siphon tube should be placed at the level on the cystometer tube found when 400 cc. of fluid have been placed in the bladder. With this attention, it will be easy to follow the course of neurologic improvement or the development of automatic reflex activity. After the atonic stage, most neurogenic bladders resulting from spinal cord injury pass into a hypotonic, then a hypertonic or normal reflex neurogenic phase. Some will rapidly become almost normal if the spinal cord has suffered only a minor concussive injury, but unless this occurs within one month it is unlikely that such will ever be the case.[26] When the bladder shows by cystometry a pressure of more than 70 cm. of water with a content of 400 cc. or less, the catheter should be removed. Administration of belladonna in full dosage may be of benefit at this time. The patient should be made to urinate at two hour intervals by using a combination of voluntary expulsive force, suprapubic tapping or actual Credé pressure and even submersion in a tub of warm water. This should be done both day and night, until daily morning catheterization shows a residual of less than 1 ounce (28 Gm.). With this goal achieved, the time interval can be lengthened gradually to four hours. Then, by restriction of bedtime fluids, the patient can spend the entir

ithout voiding and without fear of

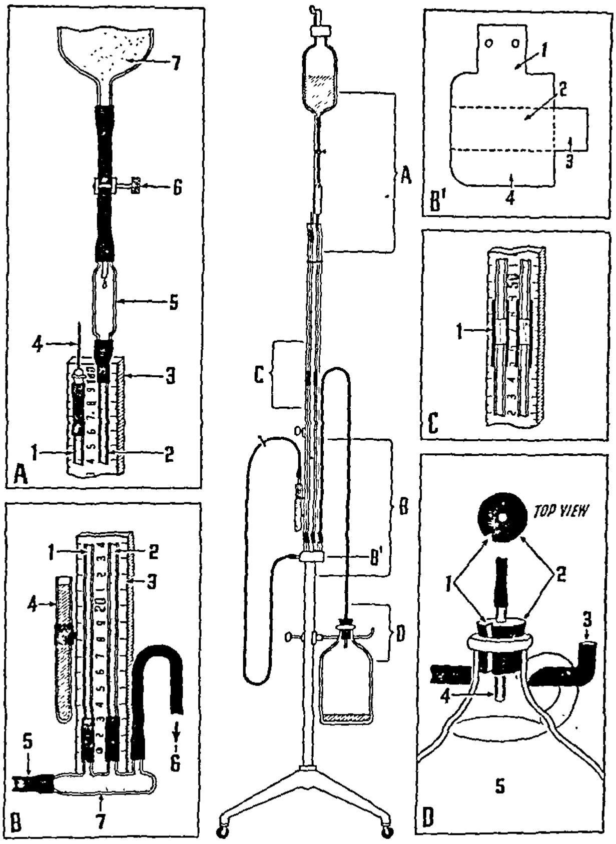

Fig. 4.—Tidal drainage apparatus. A wooden meter stick is supplied with two clips for fastening to an ordinary hospital infusion bottle stand, and small holes are drilled at 2 cm. intervals on the left side of it. At the bottom of the stick is attached a small metal trough, constructed according to panel $B^1$. Dimensions are not given because of the variation in size of Carrell-Dakin tubes, but the average folded length is about *2 inches (5 cm). In panel A: (1) top of cystometer and air inlet arm* made of 5 mm. bore glass tubing, 50 cm. in length; (2) top of drip tube of same size and length; (3) meter stick; (4) hypodermic needle (23 gage for 10 drops per minute infusion, larger for faster rates) connected to cystometer tube by snugly fitting rubber tubing; (5) Murphy drip tube without hole; (6) Hoffman or Mohr screw clamp for regulating rate of infusion, and (7) Kelly flask or other graduated bottle (empty Baxter bottles make an excellent container if the pharmacy manufactures, bottles and sterilizes the irrigating fluids) connected to Murphy drip by rubber tubing. In panel *B*, showing details at bottom end of apparatus: (1) lower section, 5 mm. bore, 50 cm. glass tubing (connected to upper sections by snugly fitting rubber tubing as shown in panel *C*) of cystometer tube; (2) lower section, same bore and length, of drip tube; (3) meter stick (1 mm. holes in side not shown); (4) glass test tube clipped *or taped to side of meter stick, filled with antiseptic solution,* which serves to receive the tube leading to the catheter when the patient is disconnected from the apparatus; (5) rubber tubing, 3/16 inch (0.48 cm.) or larger and sufficiently long to reach from stand in its desired position to the catheter with some slack, with a glass connected to the catheter *at the end; (6) siphon arm rubber tubing, 3/16 inch (0.48 cm.) inside* diameter with wall thick enough to prevent kinking and about 160 cm. long, and (7) Carrell-Dakin tube, three-way. The arrangement as shown allows the least amount of debris to collect. It is attached by snugly fitted pieces of rubber tubing to the glass tubes (1) and (2). Panel *D* shows a simple method of avoiding contamination and spillage. (2) Number 5 one-hole stopper with a notch (1) cut in the side; (3) Bent clamp to suspend bottle on stand at proper height; (4) glass tube of larger bore than 3/16 inch (0.48 cm.) tube passing at least 1 inch (2.5 cm.) beyond bottom of stopper, and (5) ordinary gallon jug.

The cystometer and drip tubes are attached to the meter stick with clips or with rubber bands. Thus, in practice, the glass tubes are disconnected from the Carrell-Dakin tube, leaving the rubber connections on the latter. The sections of glass tubing are disconnected, leaving the *needle on the one and removing the other from the connection to the* Murphy drip. When the long rubber tubing is rolled up, the entire apparatus can be contained in a sterile wrap 60 cm. long. After sterilization, the assembly is carried out as follows: The glass connector of the tube to the catheter is placed in the test tube receptacle and the *siphon-arm stopper in the sterile water bottle. The Carrell-Dakin tube* is set in the trough and the four lengths of glass tubing are attached to it. The connected glass tubes are either threaded through already attached rubber bands or are clipped in place. The apparatus is now adjusted so that the zero mark on the meter stick is approximately level with the level of the symphysis pubis in the supine patient. The infusion flask is then hung and its height is regulated to give attachment without kinking to the drip tube. It is desirable to have a toy balloon in each setup to test the efficiency of the apparatus. This is attached to the glass connector on the tube leading to the bladder. The top of the siphon arm is set at 10 cm. by means of a loop of wire arranged like a cup hook. The infusion fluid is allowed to run into the balloon fairly rapidly. When the pressure within the balloon is greater than the height of the siphon arm, the inflow is cut off. The balloon should empty completely if the waste bottle is at a distance of 26 cm. below zero level. If it does not empty completely, the waste bottle should be lowered. The apparatus can then be applied to the patient and a cystometric examination should be done (see text). An alternative but less satisfactory means of suspending the siphon arm utilizes a piece of tape and a thumb tack.

Treatment of the Bladder in Spinal
7-230 (Sept.) 1937.
Treatment of Neurogenic Bladder
th America 23: 1505-1525 (Dec.),
ation of the Urological Care of
9-455 (Oct.) 1946. (*d*) Jacobs, F.:
of the Urogenital Tract, J. Urol.

patients with atonic bladders were seen, but overdistention was the cause, for neurologic investigation revealed the intactness of the reflex arcs.[27] As such, it is indeed rare that a patient should be found who will not have a good automatic bladder, provided that meticulous attention be paid to its management.

Infection of the bladder or other parts of the urinary tract is common. Cystitis is present once a catheter is introduced into the bladder, whether through a suprapubic wound or through the urethra. However, as long as careful attention is paid to the irrigation system, this infection will be subclinical. The irrigating fluids used include solutions G (citric acid 32.25 Gm., magnesium oxide 2.92 Gm. and sodium bicarbonate [anhydrous] 3.84 Gm. per liter of distilled water) and M (citric acid 32.25 Gm. magnesium oxide 2.92 Gm. and sodium bicarbonate [anhydrous] 8.84 Gm. per liter of distilled water),[28] 2 per cent boric acid, 0.5 per cent acetic acid and others. Solution G has received wide attention and extensive use. It is probably the best all-round solution to use, although solution M has the advantage of a more favorable $p_H$ (5.0) after the first few days of irrigation. Solution G may produce inflammation after prolonged use.

Unless the urethral catheter is small enough to allow escape of secretions and is changed at weekly intervals, the subclinical infections of the urinary tract may progress to clinical complications in the lower part of the urinary tract. Most frequent of these is epididymitis, frequently encountered when catheters larger than a no. 18 F are in use. The large catheter prevents egress of fluid from and produces edematous closure of the bulbourethral, ejaculatory and prostatic ducts. The resulting stasis is favorable to infection. Inspection and palpation when fever is present makes diagnosis simple. Treatment consists of suspension of the testicles and cold packs in the early stages, and heat in the later stages if suppuration appears likely.

Actual abscess formation necessitates incision and drainage. Prompt action prevents progression, and, even in the neglected case, urinary fistulas will be uncommon, provided that the aforementioned steps are taken in conjunction with intramuscular administration of penicillin and high fluid intake. A few patients were treated successfully by infiltration of the spermatic cord [29] and the lumbar sympathetic chain [30] with procaine hydrochloride solution.

Second in frequency of development, most usually traceable to temporary occlusion of the drainage system or to overdistention of the bladder by placement of the siphon arm of the drainage system too high, are the infections of the upper part of the urinary tract. In some paraplegic patients the ureterovesical orifices are wide open, a state conducive to reflux. This has been seen in many patients subjected to chronic overdistention of the bladder, but rarely, if ever, in those cases in which overdistention was avoided. This is probably the severest indictment of the methods of treatment of bladder paralysis by overflow distention or Credé expression. With the passage of urine containing bacteria from the bladder up the open ureters, enhanced by positional stasis within the renal pelvis, various grades of renal infection are encountered, dependent on how soon the proper diagnosis is arrived at and proper treatment instituted.

Not too infrequently, positional stasis is enhanced by an actual blockage of the ureter by inflammatory ureteral atony or by opaque and nonopaque calculi. The clinical signs of infection of the upper part of the urinary tract in paraplegia include: (1) chills and temperature elevation, usually to 104 F. or above; (2) the appearance of apparent health in the face of such high temperatures, followed by the expected appearance of grave illness in a matter of hours, and (3) resistance in the flank on the involved side, or on both sides if the infection is bilateral (which appears to be usual after the first twenty-four hours).

Since no description of this resistance has appeared in the literature, a brief description is given. When the patient is examined in the supine position, pressure applied alternately and then together in the flanks will give a measure of resistance. In the spastic patient, this may be considerable, and it may be necessary to test many times before a reflex-free period is encountered to give a measure of resting resistance to pressure. The patient is then placed in the prone position and the procedure repeated. It will be found that resistance is high on the involved side. This is probably a result of ureteral inflammation with irritative effects on the psoas muscle.

Examination of the urine usually fails to keep attention directed at the urinary tract, for culture most frequently reveals only the usual Escherichia coli, Bacillus proteus, Bacillus pyocyaneus and Bacillus aerogenes—present in cultures since shortly after the catheter was inserted. However, later examination often reveals staphylococci or streptococci. This pertains because in the early phases, there is reflex or obstructive suppression of urinary drainage from the involved side. When this phase is overcome, the actual pathogenic organism is drained off, to be picked up by culture.

Treatment consists of: (1) penicillin, 20,000 to 30,000 units, intramuscularly every three hours, (2) intravenous fluids to give an output above 2,500 cc. and (3) plain roentgenogram of the abdomen in a search for possible calculous obstruction.

If calculous obstruction is demonstrated, cystoscopic examination and passage of a catheter to the renal pelvis constitute the best form of treatment. It is felt that catheterization of the involved side might well be considered in every case, for dramatic improvement is seen when drainage of the involved kidney is obtained. It might be argued that excretion urograms will provide a rational basis for selection of cases for renal catheterization. This is undoubtedly true, but the patient is often so ill that the added discomfort of this procedure makes it inadvisable, whereas cystoscopic examination can be accomplished without this discomfort and more illucidating retrograde urograms can be made if needed.

Once the progress of infection is arrested by penicillin and drainage, recovery is rapid. In the majority of cases, penicillin therapy and forced fluids will insure complete recovery. If, however, with these measures having been instituted soon after the onset of the chills (even before the diagnosis is confirmed), the temperature fails to return to normal within thirty-six hours, blockage of the involved renal pelvis is almost assured. The gram-positive organisms, controlled by the penicillin, no longer contribute to the picture, and the infection now is accompanied by a much lower temperature (100 to 103 F.). The organisms responsible are gram negative, and unless prompt action is taken to insure free drainage of the renal pelvis, the cortex may be invaded, with abscess formation resulting and progression to perirenal abscess, and further extension into neighboring structures, bacteremia and death.

In these cases, streptomycin therapy (0.4 Gm. [400,000 units] every four hours for at least seven days) is often useful, but is no substitute for adequate drainage and should be used only as conjunctive treatment. A fairly high percentage of the patients will be cured when the drainage is spontaneously established, but, if stones which obstruct fail to pass, progression of the process is to be expected. Bacteremia has been found infrequently in patients who subsequently recovered from these complications. There is no substitute for drainage of an abscess, a principle that should not be overlooked in the care of paraplegic patients.

Cystitis, as a urinary tract complication, is rarely of clinical significance, except in the neglected case. It may be bacterial or chemical, and the presence of blood cells in the urine should lead one to suspect its presence. Alkaline incrustations are common when suprapubic tubes are left in place for long periods with inadequate irrigation. These incrustations disappear rapidly when solutions G or M are used as irrigating fluids.[31] Inflammation subsides with a regimen of high fluid output, proper irrigation with solution M and meticulous care of the catheters and the orifices through which they are introduced.

Other complications encountered in the early phases of treatment include balanitis, from improper attention to the catheter and the penis. The penis should be kept clean, and a sterile gauze pad, dipped in benzalkonium chloride solution, 1:10,000, should be wrapped about the catheter at the end of the penis. Urethroscrotal fistulas may develop when the catheter size exceeds that of a no. 24 F, but may also develop with smaller ones unless kinking of the catheter is prevented.

2. *Skin.*—As previously indicated, the skin will not tolerate long periods of pressure with concomitant ischemia. The question of trophic influences and other allied explanations are trivial in relation to pressure.[32] The loss of normal sensory impulses from areas subjected to undue periods of ischemia eliminates the reflex moving response, usually carried out at a subconscious level. Sympathetic innervation can function only under physiologic or early pathophysiologic conditions, and is entirely incapable of functioning in the presence of severe tissue trauma where locally produced substances[33] produce maximum vasodilatation in the face of generalized vasoconstriction. On the contrary, vasoconstriction would be expected to be initiated by the painful impulses arising during the advent of ischemia, thus implying that normal skin should be more susceptible to decubitus ulceration. Whatever the academic answer, the practical one consists of avoidance of prolonged ischemia. Since the patient is incapable of turning himself either reflexly or voluntarily, he must be turned by attendants. The only safe rule is to turn the patient every one or two hours day and night. The development of hypoproteinemia, which leads to edema and bullous formations in the skin, also predisposes to the development of ulceration of the skin. To maintain the skin in good condition, it is essential to keep the protein intake at a high level as noted.

It is of utmost importance that the skin be kept clean and dry at all times. Soiling of the skin with urine and feces must be assiduously avoided, or promptly taken care of in case of accidental soilage. The patient must be kept on smooth, clean sheets at all times, for a single wrinkle can bring disastrous consequences. The use of quilted pads or inflated cushions or rings cannot be condoned, for they concentrate the weight bearing at a single point. Air or fluid mattresses avoid this concentration of the weight. Positioning is accomplished by the use of footboards and pillows of various sizes. The knees should always be flexed about 15 degrees in the supine and prone positions, with the feet at right angles and the heels suspended clear of the sheet. In the lateral positions, a pillow should be placed between the legs to keep the knees and ankles apart, with the feet supported at right angles with pillows. Sheets and bedclothing never should be allowed to rest on the upright toes, and likewise the toes should never support the weight of the foot in the prone position. Turning should be accomplished with a draw sheet to avoid dragging the patient across the sheets.

If a pressure area has developed, marked only by redness, it should be massaged with alcohol and sprinkled with powder. This advice is given with reservation, for the appearance of markedly reddened areas indicates that the patient cannot tolerate the amount of time that he was subjected to that degree of pressure. The tissues beneath a pressure area may become gangrenous without breaking down the skin, giving the appearance of a subcutaneous abscess. No amount of massage will retrieve gangrenous tissues. If the patient is admitted with actual decubitus ulcers (marked by blackened patches of skin), immediate debridement should be carried out. At the first debridement, excision should be carried to within about 2 mm. of normal skin and down as deep as necessary. The depth of the excision will usually be found to reach all the way to the periosteum, and special attention should be given to the areas which extend beyond the bony prominences. Excision right up to normal skin in early stages is accompanied with too much bleeding. Several days after the initial excision, the remainder of the necrotic tissue can be excised. Sterile fine mesh gauze should be lightly packed into all crevices, and dry sponges should be applied over this. Dressings should be changed in accordance with the amount of drainage present. Usually once a day will be sufficient. When dressings are changed, the wound should be cleansed with weak hydrogen peroxide, washed carefully with white soap and water and rinsed thoroughly with sterile saline solution. Dry gauze should then be reapplied. If the general outlines of therapy are carried out in conjunction with this method of handling decubiti, in about ten days granulation will be proceeding rapidly. At this point, it is important to make careful inspection of the decubitus for undermined edges, for the granulations will often wall off a pocket which soon becomes infected. All such crevices must be packed. Several points must be made in regard to infecting organisms. Generally, E. coli and B. proteus are found in cultures of these sores. The treatment outlined keeps these organisms under control. Occasionally, however, the granulations will be marked by hemorrhagic spots and blackened areas. These almost invariably denote the presence of streptococci, and intramuscular treatment with penicillin must be started. The presence on the dressings of a greenish yellow to blue discoloration denotes the presence of B. pyocyaneus. The easiest (and almost astounding) method to combat these organisms is by a thorough rinsing with 2 per cent aqueous merbromin solution. Of the many agents used on decubiti, this is the only one which can be said to be specific and apparently harmless. In regard to the application of various ointments, such as red cell paste, scarlet red ointment, tyrothricin, penicillin and sugar, plasma and penicillin, chlorophyl paste and cod liver oil, almost all will be effective in sympathetic hands—just as any wound will heal with careful supervision. No ointment yet used has any advantage worthy of special mention. Yet, none will particularly retard the process of healing, and none should be marked for special condemnation. On the other hand, any substance believed to be beneficial should be used, for it will certainly help the sore get its proper attention—cleanliness. Dry treatment still remains the method of choice.

---

[33] Lewis, T.: The Blood Vessels of the Human Skin and Their Responses, London, Shaw & Sons, Ltd., 1927.

Once granulation begins, one must decide whether to await healing by using dressings or to proceed with surgical treatment. Any sore with dimensions greater than 3 cm. in depth or 5 cm. in diameter can be expected to take more than six months to reach healing. Thus, very small sores can be treated with dressings alone. However, the superiority of surgical methods is unquestionable.[34] Skin grafts—including small deep, postage stamp and split thickness grafts—have several unfavorable features. The main one is the undesirably thin scar left over the bony prominence. The only point in favor of grafting is that a temporary skin dressing is obtained. However, provided that evidences of healing are present, the patient is in positive nitrogen balance and pronounced spacticity or flexor spasms are not present, surgical excision of the entire ulcer with plastic rotation flaps is highly successful and should be used on almost every severe decubitus.[32] For superficial sores, there is nothing superior to sunlight and fine mesh dry dressings. Skin grafts hasten the healing of these sores and provide a fairly good permanent covering.

The patient must be constantly reminded of the hazards of prolonged weight bearing. Eventually, the patient will be the best one to determine how long he can maintain a given position without embarrassing his skin.

3. *Bowel.*—Coincident with the severe disruption of reflex action in the limbs and bladder, the bowel likewise loses its reflex function. In the early stages an actual ileus may exist. In lower cord injuries this may not become obvious for many hours and most frequently resolves of its own accord. However, in cervical cord injuries, death may result from this complication. With the entire load of respiratory exchanges thrown on the diaphragm, distention in the abdomen is not tolerated. Diminution of diaphragmatic excursions decreases the respiratory exchange and leads to hypostatic accumulations of fluid, pneumonitis and death. Percussion of the abdomen and stethoscopic examination will make the diagnosis obvious. One cubic centimeter of neostigmine methylsulfate, 1 : 4,000, given every one to two hours for three to six doses, will usually resolves the ileus.[35] Posterior pituitary extract or beta-hypophamine in doses of 0.5 to 1.0 cc. are much more effective but carry a bit more danger of undesirable side reactions. Warm enemas are frequently helpful, and a rectal tube often brings dramatic relief. It has been necessary only on rare occasions to use drugs for relief, the rectal tube most usually being all that is needed. The rectal sphincter, like the external urethral sphincter of the male, is usually tightly closed after spinal cord injury and is relaxed only when the fourth sacral nerve, or the conus medullaris, is directly damaged. In later stages, the sphincter regains reflex action as does the bowel. As demonstrated by Denny-Brown and Robertson[36] and White,[37] the bowel has activity very similar to that of the bladder. In the first few weeks, enemas of warm water and soap suds should be given every other day with regularity. Digital examination should be done at least weekly, for impactions are frequent. A case which strongly emphasizes this is related briefly.

G. L., a 26 year old infantry private, sustained a gunshot wound of the lumbodorsal region with the wound of exit at the umbilicus. Motor and sensory paralysis from the waist down was immediate, and bowel and bladder control were lost. Laparotomy, with repair of perforated segments of bowel, followed by laminectomy, was carried out. Within two weeks the patient was started through the chain of evacuations from the Southwest Pacific Area. About one month later, he was admitted to a neurosurgical center in the states. On perusal of the records, it was found that the patient, in addition to the inevitable malaria and discoloration due to quinacrine hydrochloride, suffered from some "rare disease of the abdominal lymph nodes." On examination, these "lymph nodes" were found to indent. Roentgen examination of the abdomen revealed the presence of twenty-one partially calcified fecal masses, each the size of a tennis ball. These were removed manually in the course of four days.

As the bladder function begins to develop automaticity, a bowel control program should be instituted. This program is roughly as follows:

As soon as the patient can sit up, enemas are given in that position. Laxatives should be given in the form of 5 to 15 cc. of liquid petrolatum and/or 2 to 6 cc. of cascara sagrada given the previous day. In a short time, the patient should be given the duty of administering his own enemas and doing his own digital examinations for possible impactions. The patient then starts a schedule of liquid petrolatum and cascara sagrada each evening, judging the dosage by the consistency of the stools. Every morning, at exactly the same time, a glycerin suppository should be inserted up to fifteen minutes before the patient gets on the stool. A full hour should be spent before the trial at evacuation is ended. If no stool has resulted, the patient should take 2 cc. of cascara sagrada and go about his daily activities. The usual laxative is taken at bedtime. On the following morning, the procedure is repeated. If no stool results from this effort, an enema should be taken. The entire procedure is then begun again. In a few weeks, regular daily bowel movements will be established and enemas will be needed rarely. Foods are briefly outlined to the patient in regard to their effect on stool consistency ("looseners"—prunes, fruits and roughage; "binders"—cheese, meat, beans and other protein-rich foods). It is pointed out also that inactivity and drugs such as morphine and codeine give hard stools. Emotional upsets and many patent medicines give loose stools. Although much straining is necessary in early stages of training, regularity leads to less. A corset or abdominal binder is often useful. If hemorrhoids develop, repair should await regular bowel habits. There need be no acceptable end result in regard to bowel function other than full control with regular evacuations.

*(To Be Continued)*

# Clinical Notes, Suggestions and New Instruments

## URINARY OBSTRUCTION DUE TO TRIPELENNAMINE HYDROCHLORIDE

SAMUEL A. WOLFSON, M.D.
Los Angeles

Various side reactions from the use of tripelennamine hydrochloride (pyribenzamine® hydrochloride) have been observed.[1] Drowsiness, dizziness, gastric disturbances and headache have been the responses most commonly evoked. Less frequent in occurrence have been urinary burning and urinary frequency. In none of these reports has there actually been a description of a case involving urinary difficulty. I recently saw a patient whose reaction to tripelennamine involved the urinary tract and was so unusual that it appears worth recording.

### REPORT OF CASE

On Feb. 25, 1949 a white man aged 54 complained of difficult urination of three days' duration. He had been examined periodically, and there was no reason to anticipate the occurrence of the predicament.

Urination was of an obstructive character but was completely painless. Only a dribbling stream was possible. When the urethra was compressed against straining, thereby increasing the bladder pressure, the stream became full for about three seconds; as soon as the pressure reduced itself the dribbling returned.

Except for a mild rash of the face the physical examination, especially of the prostate and external genitalia, revealed essentially normal conditions. Urinalysis was normal, as was the determination of residual urine in the bladder.

In the search for an explanation for the sudden appearance of the complaint it was learned that the rash had been attributed to an allergy and was being treated with vaccine injections plus tripelennamine hydrochloride, 50 mg. tablets four times a day. Therapy had been started on February 22, and the urinary disturbance had developed within twenty-four hours.

Cardiospasm due to this drug had previously been observed; hence, it appeared not unlikely that a similar spasm of the vesical sphincter could occur. The tripelennamine was discontinued, and the urinary symptoms completely abated by the next morning.

To prove the validity of the assumption that the distress was due to the antihistaminic agent, it was planned to attempt to reproduce the condition at a later date. Accordingly, the patient was observed for two months, during which time the rash cleared, all vaccine therapy was discontinued and urinary function remained normal. On May 3, 1949, the patient received 50 mg. of tripelennamine hydrochloride at 7 a. m. and again at noon. At about 4 p. m. the urinary difficulty had reappeared. No more of the drug was administered. The symptoms rapidly subsided, were not present the following morning and have not returned to date. Measurement of residual urine in the bladder on May 11, 1949, was normal.

### COMMENT

Urinary disturbances such as dysuria and frequency have been listed among the side reactions from tripelennamine.[1a] The possible mechanisms through which these may occur have received little attention. Sherrod, Loew and Schloemer,[1b] investigating the pharmacologic properties of diphenhydramine hydrochloride (benadryl®) and tripelennamine hydrochloride on the dog intestine and uterus, found that the two antihistaminic agents had opposite actions. Diphenhydramine produced an antispasmodic effect, but tripelennamine acted as a spasmogenic agent and contracted the duodenum and uterus. The latter action could reasonably explain the gastric symptoms experienced by some patients. Similarly, a spasmogenic effect on the vesical sphincter in the present case could account for the urinary disturbance.

The ease with which the disturbance was reproduced leaves little doubt that tripelennamine was the noxious agent. It was not deemed fair to the patient to subject him to unnecessary and strenuous urologic investigation. However, others may be in an advantageous position in the future to pursue such investigation and derive much information concerning the effect of this agent on the urinary bladder.

### SUMMARY

A case of urinary obstructive symptoms believed to be due to tripelennamine hydrochloride (pyribenzamine®) is reported. The spasmogenic property of the antihistaminic agent indicates its probable relation to the urinary distress.

6333 Wilshire Boulevard (36).

# Council on Physical Medicine and Rehabilitation

## REPORTS OF THE COUNCIL

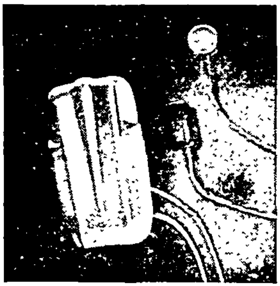
*The Council on Physical Medicine and Rehabilitation has authorized publication of the following reports.*

Howard A. Carter, *Secretary.*

## RADIOEAR PERMO-MAGNETIC HEARING AID (MULTIPOWER MODEL) ACCEPTABLE

Manufacturer: E. A. Myers and Sons, Radioear Building, 306-08 Beverly Road, Mt. Lebanon, Pittsburgh 16.

The Radioear Multipower Electronic three tube hearing aid is a two piece instrument consisting of amplifier case with separate batteries. The case is constructed of either smooth ivory or black plastic material. A magnetic type microphone and magnetic air and bone conduction receivers are utilized in the construction of the instrument. Sound pressure variations reach the magnetic microphone diaphragm through recessed louvers on the sides of the upper part of the case. This instrument is equipped with a "Phonemaster" coil with which voice signals from the telephone may be picked up inductively, amplified through the instrument, and reproduced in either the air or bone conduction receiver. A wheel type combination "on-off" switch and volume control is located at the top of the case. A "Noisemaster" switch is located on one side of the case which attenuates the high and low frequency ends of the sound spectrum simultaneously for use in noisy environments if desired. The frequency response of the microphone also can be varied by opening or closing a small hole with a screw in the microphone housing within the amplifier case. Three position, separate "Hi" and "Lo" tone controls are accessible within the interior of the amplifier case. A "Powerizer" switch by means of which the maximum gain of the instrument can be controlled over a 15 decibel level if desired also is accessible from the interior of the case. A wide range of B battery voltages and of A and B battery size may be used with this instrument.



Radioear Permo-Magnetic (Multipower) Hearing Aid

*Case Dimensions.*—106 by 60 by 25 mm. (4 3/16 by 2 3/8 by 31/32 inch).

*Case Weight,* including cords and A.C. receiver but less batteries.—170 Gm. (6 ounces).

The following table states the battery drain measured on an instrument equipped with a no. 507 type output tube:

| Battery Drain | Measured Voltage | Measured Current Milliamperes |
|---|---|---|
| A, zinc and carbon, 1.5 volts | 1.3 | 60 |
| B, zinc and carbon, 15 volts | 14 | 0.19 |
| B, zinc and carbon, 22.5 volts | 21 | 0.38 |
| B, zinc and carbon, 33 volts | 31 | 0.66 |
| B, zinc and carbon, 45 volts | 43 | 1.02 |

The instrument can also be fitted with a no. 522 output tube that results in a total filament drain of only 40 milliamperes and whose "B" battery drain is roughly two thirds of the values given in the table.

| Acoustical gain for pure tones: | 250 | 500 | 1,000 | 2,000 | 3,000 | 4,000 | cycles |
|---|---|---|---|---|---|---|---|
| Maximum gain, air conduction | 40 | 50 | 62 | 70 | 70 | 40 | decibel |

(The preceding measurements were obtained with the Powerizer set at plus 15, both tone controls at plus and a 43 volt B battery).

*Acoustic Gain for Speech.*—Two experienced adult hearing aid users, each with predominantly middle ear impairments of approximately 50 db., each perceived speech at a 50 db. lower level by air conduction and 42 db. lower level by bone conduction as measured with a speech audiometer. (Note: the above does not necessarily indicate the maximum acoustical gain for air conduction. Patients with greater air conduction losses than the ones available to the referee would be needed for such a speech test with this instrument).

*Evaluation.*—The Radioear Multipower Permo-Magnetic Hearing Aid is a well constructed instrument with several features of value to hearing aid users. The "Phonemaster" permits the reproduction of telephone speech at least 15 decibels higher level in the hearing aid receiver than that in a telephone receiver. The "Powerizer" reduces the gain approximately 15 decibels if desired, and the use of different B battery voltages permits any desired power output up to the maximum attainable with the 45 volt B battery. The "Noisemaster" attenuates frequencies below approximately 1,000 cycles and above approximately 2,000 cycles for use in noisy environments if desired. The separate "Hi" and "Lo" frequency adjustments plus the adjustment of the frequency response screw on the microphone case permit a very flexible control of the frequency response of the instrument.

The Council on Physical Medicine and Rehabilitation voted to include the Radioear Permo-Magnetic Hearing Aid, Multipower Model, in its list of accepted devices.

## RV 6-WATT PORTABLE BLACK LIGHT ACCEPTABLE

Manufacturer: Vogel Luminescence Corp., 260 Napoleon Street, San Francisco 24.

The RV 6-Watt Portable Black Light is a convenient source of ultraviolet light for diagnostic purposes, such as the inspection of the scalp for tinea capitis. It consists of a standard General Electric 6 watt, 360 BL fluorescent lamp, mounted in a housing, 6.4 by 6.4 by 23 cm. (2½ by 2½ by 9 inches), and weighing about 1 Kg. (2¼ pounds). The shipping weight is 1.1 Kg. (2½ pounds). It can be operated only on 60 cycle, 110-120 volt alternating current. For D.C. or 50 cycle operation special equipment is needed. Through a long, flexible conducting wire the device can be connected to any standard electric wall outlet. The rated life is stated to be from 1,000 to 2,000 hours, depending on the number of starts.

The source of ultraviolet is a glass tube, lined with a thin coating of 360 BL powder which is excited to light emission by a low pressure mercury arc discharge, principally by wavelength 2537A. This powder has the property of emitting ultraviolet radiation in the band of wavelengths extending from about 3,000 angstroms to 4,200 angstroms in the visible spectrum. The unwanted visible light from this source is removed by surrounding the fluorescent glass tube with a tubular Corning red-purple glass filter no. 5874 that transmits about 70 per cent of the 3,660 angstrom emission, which is the most effective band of wavelengths for exciting fluorescence of objects as in the identification of minerals and the examination of the scalp.

Radiometric measurements, made in a laboratory acceptable to the Council, of the radiation of all wavelengths extending from 3,000 to 4,200 angstroms indicated a radiant flux density (intensity) of 9.26 milliwatts per square centimeter at 17 inches and 3.40 milliwatts per square centimeter at 40 inches from the front of the lamp. Covered with the Corning filter, the intensity in the waveband at 3,660 angstroms is much lower, but as used close to an object under examination the intensity is sufficient.

In addition to the aforementioned laboratory tests, the specimen was subjected to practical clinical trials. Satisfactory evidence of dependability and usefulness was obtained.

The Council on Physical Medicine and Rehabilitation voted to include the RV 6-Watt Portable Black Light in its list of accepted devices.

SATURDAY, JULY 16, 1949

## THE PRINCIPLES OF ETHICS OF THE AMERICAN MEDICAL ASSOCIATION

Almost unnoticed in the midst of the startling developments of the Atlantic City Session was the presentation by the Judicial Council to the House of Delegates of a restatement and revision of the Principles of Medical Ethics. This statement was promptly adopted by the House of Delegates. Comparison will indicate the additions and changes that have been made in content and in manner of statement. Among the most significant changes are those relating to groups and clinics, including contract practice, the section on educational information and the section on the purveyal of medical service.

The report of the Committee on Hospitals and the Practice of Medicine took its guidance from the Principles of Medical Ethics as last revised in 1940 rather than from the new statement which was adopted in this 1949 Session. No doubt further considerations by this committee in the period between now and the Clinical Session of the Association which will be held in December will result in coordination of these actions.

In the case of the Government versus the American Medical Association tried in Washington in 1941, the courts took cognizance of the Principles of Medical Ethics as a guide to physicians in relationship to the adoption of any methods of medical practice. The Court recognized that members of the American Medical Association voluntarily subjected themselves to the stipulations of the constitution and by-laws of county and state societies, of the American Medical Association and also to the Principles of Medical Ethics.

The statements now prevailing permit experimentation with changes in the method of medical practice beyond some restrictions which prevailed formerly. No doubt the Judicial Council will have opportunity to interpret the statements now made in relation to specific incidents as these arise. Ethics as stated in the introduction to the principles "are not laws to govern but are principles to guide to correct conduct." "An upright man, instructed in the art of healing" seldom needs to refer to the Principles of Medical Ethics in making his decisions as to the manner in which he conducts his practice and his life.

The fundamental principle that the physician shall not dispose of his professional attainments or services under terms or conditions which permit exploitation of the services for the financial profit of a corporation or lay agency still obtains. The only type of contract practice specifically condemned is that which may result in deterioration of the quality of the medical services rendered.

Instances have occurred in which physicians, for political, commercial or emotional reasons, have endeavored to utilize the Principles of Medical Ethics as a means of producing embarrassment, distress or loss of reputation of other physicians whom they envy or whose open competition they fear. The Principles of Medical Ethics were not designed for any such purpose, and the attempt to utilize the principles of ethics for such purposes may well be in itself unethical.

Shortly the Principles of Medical Ethics will become available in the form of a newly designed booklet, which may be secured from the office of Secretary George F. Lull. Physicians should become familiar with the principles, since raising the moral standard of the medical profession is one of the fundamental aims of the American Medical Association.

## ACTIONS OF THE HOUSE OF DELEGATES

Several decisions of the House of Delegates in Atlantic City will affect the practice of the physician and the medical care of the people of the United States.

Resolutions brought before the House of Delegates and reports of boards, councils and committees are referred by the speaker of the House to an appropriate reference committee, which in turn brings its report to the House for ratification. The House of Delegates may then accept the report, reject it or amend it. Those interested in the ultimate actions of the House of Delegates will do well, therefore, to begin with the reports of the reference committees and refer back to the resolutions concerned.

### Fees for Insurance Examinations

More than 95 per cent of the $13,000,000 paid by life insurance companies to practicing physicians in 1948 was for examinations. The Bureau of Medical Economic Research made a study of the problem supplemented by a survey which was conducted under the auspices of the Association of Life Insurance Medical Directors. The reference committee to which this report was referred suggested that it be sent to the secretaries of the constituent associations for study.

### Hospitals and the Practice of Medicine

The Committee on Hospitals and the Practice of Medicine presented to the House of Delegates a consideration of the corporate practice of medicine with the conclusion that it is illegal, with some minor exceptions, and unethical for any lay corporation to practice medicine and to furnish medical services for a professional fee, which shall be so divided as to produce profit for a lay employer, either individual or institutional. This statement, which went to the reference committee on the Report of the Board of Trustees, brought forth the view that hospital service plans shall provide payment for hospital services only and that medical service plans shall supply payment for all medical services, including pathologic, roentgenologic, anesthesiologic and physical therapeutic services. Every physician on the appointed staff of a hospital, the committee believed, should have a voice in its professional management. The conclusion was that most controversies between management and the professional staff should be settled on local levels and that every constituent state and territorial society should appoint a committee on hospital and professional relations. The reference committee said that it was within the power of the Judicial Council to find a hospital or lay group guilty of violating the Principles of Ethics and recommended that the Judicial Council order the withdrawal of the Association's approval of a hospital which did not comply.

### Prepayment Medical Care

The Council on Medical Service, recognizing the great progress made in voluntary prepayment medical and hospital care plans, reported that the American Medical Association is not engaged in the insurance business and has no intention of giving a preferential standing to any one type of voluntary plan. The Association does, however, evaluate insurance plans with a view to protecting people against unscrupulous or unsound plans.

The Council on Medical Service recommended the formation of a national coordinating agency to represent all qualified voluntary prepayment plans. The Council recommended that there should be no official connection between the American Medical Association and the Associated Medical Care Plans, but that Associated Medical Care Plans should be recognized as a trade organization of member plans and the Blue Cross as a similar trade organization for the voluntary hospital care plans.

The Council feels that the function of the American Medical Association is to promote the principle of voluntary insurance by education and to inform the American people of the availability of approved plans. The Council on Medical Service also recommended twenty principles for lay-sponsored voluntary health plans, indicating its belief that these should comply with the Principles of Ethics of the American Medical Association and be adequately financed. Under these principles promotion, sales, organization and administrative expense must be kept at a minimum and the quality of the medical service must be maintained at the highest possible level. The twenty points, which were published in THE JOURNAL, June 25, page 686, indicate that the plans shall provide for services by duly licensed physicians only and that those practicing specialties shall be required to have adequate qualifications for the specialties. The promotional material is not to invite attention to the professional skill, qualifications or attainments of participating physicians. The methods of payment of the physicians shall not be contrary to the Principles of Ethics. Any plan desiring approval is to agree to periodic reviews and to abide by such regulations as may be deemed necessary by the appropriate accrediting body of the American Medical Association. This report was referred to a reference committee on insurance plans, which pointed out that the twenty points had been tentatively initiated jointly by representatives of the Council on Medical Service and the Cooperative Health Federation of America. The reference committee added as a final criterion the recommendation that "any lay-sponsored plan desiring approval by a proper accrediting body of the American Medical Association shall come bearing the endorsement of the state or county medical association involved."

### Health Plan for the United States

A resolution was proposed offering a health plan for the United States with ten major points, and the reference committee indicated that this was a matter for study by the Council on Medical Service.

### Classification of Medical Schools

The Council on Medical Education and Hospitals requested approval by the House of Delegates of a consideration of foreign medical schools with a view to aiding state licensing boards in establishing their policies with respect to licensure of foreign graduates. The Council on Medical Education and Hospitals also submitted to the House of Delegates some new standards for residency training in physical medicine and rehabilitation and indicated that it had approved the newly formed American Board of Preventive Medicine and Public Health. The reference committee recommended adoption of the report of the Council on Medical Education and Hospitals.

Many resolutions on medical education were introduced by delegates from various states. The reference committee took action, which was supported by the House of Delegates, leading to the following procedures: (1) graduate and postgraduate education for general practitioners should be made more widely available; (2) two year rotating internships should be especially designed for those who wish to train for general practice, and (3) the American Medical Association should most urgently insist that hospitals make freely available to qualified general practitioners all their facilities for the care of the sick.

The committee recommended that a committee of five members of the House of Delegates, two of whom shall be general practitioners, be established to study the whole internship problem and especially to study the advisability of recommending the two year rotating internship. Finally the committee recommended the adoption of a resolution to the intent that the Council on Medical Education and Hospitals shall extend its inspection service to all hospitals, recognizing, however, while the objective is desirable, that the performance may be beyond the scope of the Council.

### *Possible Increase in Dues and Assessments*

An attempt was made to establish dues in the American Medical Association and to provide for further assessments, but the House of Delegates advised study by the Board of Trustees and delay in action until the Interim Session.

### Displaced Physicians

A resolution urging cooperation of the American Medical Association through appointment of a committee to study the problem of displaced physicians in cooperation with other agencies that have this problem as one of their functions was approved, if feasible.

Another resolution urging the appointment of a special committee to work on the problem of displaced physicians was referred to the Board of Trustees for their disposition.

### General Practitioner's Award

A resolution was introduced suggesting the abandonment of the annual award of a medal to a leading general practitioner. The House of Delegates, however, decided to continue this award.

### Emergency Medical Service

Congratulations are due the Council on National Emergency Medical Service, which apparently has functioned successfully to secure the establishment of a civilian physician at an important level in the office of the Secretary of Defense. Dr. Raymond B. Allen, present president of the University of Washington, will occupy the position for three months and will be succeeded by Dr. Richard L. Meiling of Columbus, Ohio, who has devoted himself with great personal sacrifice to the work of this Council.

### A.M.A. Hearings on Taft and Hill Bills

Resolutions were offered expressing the attitude of the American Medical Association toward the legislation proposed in the United States Senate by Senator Hill and Senator Taft offering proposals for the extension of medical care. The reference committee recommended that the resolutions be committed to the Board of Trustees with a request that it fix a day on which it will hold hearings on the resolutions at which any person may appear to present his views. The resolutions in question came from the delegates of the state of Pennsylvania.

## Current Comment

### HEARINGS ON HEALTH LEGISLATION

With the beginning of the recent hearings on health legislation by the Subcommittee on Health of the Committee on Labor and Public Welfare, the importance of the situation and general medical interest seemed to warrant a full report in The Journal such as has been included for previous hearings. However, both legislators and the medical profession seem to have lost much of their interest in these hearings, and reports indicate that hardly a visitor attended the hearings during the last three or four weeks before they were adjourned. Accordingly, The Journal discontinues the publication of the condensation of the hearings. Those who are especially interested may obtain the full reports which will no doubt be made available as in the past by the Government Printing Office. Copies may also be obtained through the Washington office through Dr. Joseph S. Lawrence, 1302-18th Street, N.W., Washington 6, D. C.

### CARE SENDS BOOKS

The Cooperative for American Remittances to Europe has now undertaken a new function which is of great interest to the medical profession. The program is designed to replenish the shelves of libraries in professional schools and other libraries abroad with gifts of new American technical and scientific books. Cooperating in the plan are the United States Commission for UNESCO, the Library of Congress, the American Library Association and the United States Book Exchange. The Board of Trustees of the American Medical Association has also approved the project and expresses the hope that physicians will contribute to CARE[1] for this purpose. A distinguished group of American physicians has been appointed to select the books that are best suited to the purpose, and American medical publishers are cooperating by making the best possible price on the books selected. The bibliography committee is headed by Dr. Luther Evans, who is librarian of Congress. Only new books will be sent; used books cannot be accepted. All books will be in the English language. Incidentally, 85 per cent of requests for scientific and technical books received by UNESCO are for books printed in English. Donors of $10 or more may designate the country, the institution or the category of books to be sent. They will receive from the foreign recipient a letter acknowledging receipt of the gift; gifts of less than $10 will be pooled in a general book relief fund, and donors will receive an acknowledgment but not a receipt signed by the recipient.

---

[1] CARE headquarters are at 20 Broad Street, New York 5.

# ORGANIZATION SECTION

## *Official Notes*

### THE SCIENTIFIC EXHIBIT, WASHINGTON, D. C., SESSION, DEC. 6-9, 1949

Application blanks for space in the Scientific Exhibit at the Washington Session, Dec. 6-9, 1949, are now available. The meeting is intended primarily for physicians in general practice and will consist of clinical presentations accompanied with exhibits of practical interest:

The Scientific Exhibit will include many exhibits with active demonstrations.

Application blanks may be obtained from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn St., Chicago 10, Ill.

COMMITTEE ON SCIENTIFIC EXHIBIT
DWIGHT H. MURRAY, *Chairman.*
E. J. MCCORMICK.
F. J. L. BLASINGAME.

### REVISED EDITION OF MOTION PICTURE REVIEWS NOW AVAILABLE

The Committee on Medical Motion Pictures has completed the first revised edition of the booklet entitled "Reviews of Medical Motion Pictures." It now contains all the film reviews published in THE JOURNAL to Jan. 1, 1949. It also includes a classified table of contents as well as a list of motion pictures available through the Motion Picture Library, American Medical Association.

The purpose of the reviews is to provide a brief description and evaluation of motion pictures which are available to the medical profession. Each film is reviewed and commented on by competent authorities.

One copy has been mailed to the secretary of each county and state medical society. Additional copies are available on request from the Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago 10.

## *Woman's Auxiliary*

The twenty-sixth annual meeting of the Woman's Auxiliary held in Atlantic City, N. J., June 6-10, 1949, was an outstanding success both from the point of view of attendance and program. The registration was 1,583. Proceedings of the convention will be published in the August 1949 *Bulletin.*

### NATIONAL OFFICERS AND CHAIRMEN

National officers and chairmen of standing committees for 1949-1950 are as follows:

President—Mrs. David B. Allman, 104 St. Charles Place, Atlantic City, N. J.
President-Elect—Mrs. Arthur A. Herold, 731 Oneonta Street, Shreveport, La.
Vice Presidents
  First—Mrs. Harold F. Wahlquist, 129 W. 48th Street, Minneapolis.
  Second—Mrs. Henry Garnjobst, 508 Jefferson St., Corvallis, Ore.
  Third—Mrs. W. E. Hoffman, 4000 Noyes Ave., S.E., Charleston 5, W. Va.
  Fourth—Mrs. Mason G. Lawson, 200 Ridgeway, Little Rock, Ark.
Treasurer—Mrs. George Turner, 3009 Silver St., El Paso, Texas.
Constitutional Secretary—Mrs. Harry M. Gilkey, 4941 Westwood Road, Kansas City, Mo.
Directors:
  One year
    Mrs. Luther H. Kice, 95 Brook St., Garden City, Long Island, N. Y.
    Mrs. James P. Simonds, 2033 W. Morse Ave., Chicago 45.
    Mrs. Jesse D. Hamer, 1819 N. 11th Ave., Phoenix, Ariz.
    Mrs. Leo J. Schaefer, 700 Highland, Salina, Kan.
  Two years
    Mrs. Scott C. Applewhite, 240 Bushnell St., San Antonio 2, Texas.
    Mrs. Ralph Eusden, 4360 Myrtle Ave., Long Beach 7, Calif.
    Mrs. William W. Potter, 129 Kenesaw Terrace, Knoxville, Tenn.
Chairmen of standing committees
  Finance—Mrs. Scott C. Applewhite, 240 Bushnell St., San Antonio 2, Texas.
  Hygeia—Mrs. Herbert W. Johnson, 741 Grand Ave., Everett, Wash.
  Legislation—Mrs. Bruce Schaefer, 110 Whitman St., Toccoa, Ga.
  Organization—Mrs. Harold F. Wahlquist, 129 W. 48th St., Minneapolis.
  Program—Mrs. Leo J. Schaefer, 700 Highland, Salina, Kan.
  Publications—Mrs. James P. Simonds, 2033 W. Morse Ave., Chicago 45.
  Public Relations—Mrs. Paul C. Craig, 232 N. Fifth Street, Reading, Pa.
  Revisions—Mrs. Eustace A. Allen, 18 Collier Road, N.W., Atlanta, Ga.
Special Committee
  Reference—Mrs. Rollo K. Packard, 14093 Davana Ter., Sherman Oaks, Calif.
Historian—Mrs. Jesse D. Hamer, 1819 N. 11th Ave., Phoenix, Ariz.
Parliamentarian—Mrs. William E. Dodd, Bay Avenue and Ocean St., Beach Haven, N. J.

### REVISIONS

The revisions to the by-laws, which accompanied the call to meeting and were published in the *Bulletin,* were presented to the House of Delegates. The action taken was that they be tabled indefinitely.

### RESOLUTIONS

Three resolutions were adopted by the House of Delegates: (1) That the Woman's Auxiliary adopt the American Medical Association 12 point program as a part of the Auxiliary program; (2) in memory of three deceased past national presidents, Mrs. James Blake, Mrs. Robert W. Tomlinson and Mrs. Franklin Gengenbach; (3) re: approval of voluntary prepayment medical insurance.

### MEMBERSHIP

Membership of the Auxiliary as of June, 1949, as reported by the Organization Committee, is 48,659, an increase of 6,237 members over last year.

### BUDGET

The budget for the year 1949-1950 of $34,493 was approved. It will be published in detail in the *Bulletin.*

### "THE DOCTOR'S WIFE"

Plans for the new magazine to be published by A. M. A. for the Woman's Auxiliary have been postponed indefinitely.

### THE BULLETIN

The Board of Directors recommended that all state and county presidents be requested to appoint county and state *Bulletin* chairmen, and to use their influence in stimulating interest in the Auxiliary official publication. It was suggested that every working member be urged to subscribe. The rate is $1 per year for four issues. Subscription blanks and information will be forwarded to state *Bulletin* chairmen from the Auxiliary office shortly.

### "THE DOCTOR"

Copies of "The Doctor," by Sir Luke Fildes, are being sent to the members of the American Medical Association on request. Whitaker and Baxter, directors of the A. M. A. National Education Campaign, have solicited the aid of the members of the Woman's Auxiliary in seeing to it that these pictures are hung in every doctor's office, preferably framed.

### 1949 CONFERENCE

The 1949 Conference of State Presidents and Presidents-Elect and the National Chairmen of Standing Committees will be held in Chicago, Nov. 3-4, 1949 at the Hotel LaSalle. Detailed information will be forwarded at a later date.

### COMING MEETINGS

American Medical Association House of Delegates Interim Session, Washington, D. C., Dec. 6-9, 1949. American Medical Association Annual Meeting, San Francisco, June 26-30, 1950.

### LISTS OF STATE OFFICERS AND CHAIRMEN

The executive secretary would appreciate the state presidents' forwarding names and addresses of the state officers and chairmen of standing committees as soon as such names are available. Programs of the national chairmen will be ready for distribution shortly.

MARGARET N. WOLFE, *Executive Secretary.*

# Washington Letter

*(From Our Regular Correspondent)*

July 11, 1949.

### House Hearings

Five weeks of public hearings on national health legislation were ended on June 29 by the Murray subcommittee of the Senate Labor and Public Welfare Committee. Those which have been conducted since May 20 by the Priest subcommittee of the House Interstate and Foreign Commerce Committee are continuing, with likelihood that they will not be terminated before the summer adjournment of Congress.

In the course of its three final sessions, on June 27, 28 and 29, the Senate subcommittee heard additional testimony in opposition to and support of compulsory health insurance and in support of the Flanders-Herter bill (S. 1970) on federal-state subsidization of voluntary prepayment plans. Other witnesses urged that greater recognition be given, in whatever legislation may be enacted, to the osteopathic and chiropody professions.

Meantime, the Priest subcommittee was gathering statements and oral testimony on Title III of the Thomas-Murray-Dingell bill (S. 1679), along with numerous independent bills, all relating to expansion of the Hill-Burton hospital survey and construction act. The majority of the witnesses were members of Congress seeking maximum benefits for hospital projects in their various states.

Its hearings now terminated, the Murray subcommittee is now engaged in redrafting certain health legislation, with the view of having it enacted in the final weeks of this first session of the 81st Congress. In the forefront are bills providing for government assistance to medical, dental and nursing education, to local public health units and to states requiring financial aid for enlarging hospital systems. These are relatively noncontroversial issues, and strong effort will be made to have such steps made into law before adjournment.

### Senator Murray Attacks Dr. Hawley on Kaiser-Permanente

A statement of opinion by Dr. Paul R. Hawley, to the effect that he does not care for Henry J. Kaiser's medical care system on the West Coast, has been made the vehicle for Senator James E. Murray's latest attack on American medicine. On July 6 he obtained Senate consent to introduce into the Congressional Record a three page statement criticizing Dr. Hawley, who is not named, plus a lengthy letter from Mr. Kaiser and an accompanying brochure describing the Permanente Health Plan sponsored by the industrialist.

In the course of interrogation by Senator Murray when Dr. Hawley testified before the Senate health subcommittee on May 31, the latter stated that the Kaiser system of salaried medical staffs is not good. The subcommittee chairman subsequently relayed Dr. Hawley's observation to Mr. Kaiser and solicited a reply. In his response, Mr. Kaiser cited the growth of the Permanente system in San Francisco, Oakland, Portland and other West Coast cities, making no reference to the opinion expressed by the executive officer of Blue Shield and Blue Cross.

Senator Murray's ensuing statement extolled the Kaiser-Permanente Plan, which he likened to the Mayo and Lahey Clinics. These are superior, he said, to "medical society health plans (which) offer absolutely no assurances of quality medical care." Noting that Mr. Kaiser opposes compulsory health insurance and favors group practice, prepayment plans instead, Senator Murray went on to say that health insurance is essential, nevertheless, to guarantee the launching and successful development of such enterprises.

### "Who's Who in World Medicine" Curbed by U. S.

Federal Trade Commission has clamped down on the advertising promotion of "International Who's Who in World Medicine," entering into stipulations with its publisher which will result in certain practices' being eliminated, according to an official announcement by FTC headquarters. One is discontinuance of "American Universities" in the publisher's corporate name—"American Universities Medical Research Publications, Inc."—inasmuch as "there are no universities in America that are financially interested in or that participate in the preparation of their publications." Another stipulation is that the company shall stop representing that "International Who's Who in World Medicine" is predominantly comprised of biographic sketches of living persons who are prominent in world medicine.

### Chiropractic in Veterans Administration Opposed

Officials of the Veterans Administration voiced emphatic objection to proposed legislation (S. 2025) authorizing appointment of chiropractors to VA's department of medicine and surgery at a public hearing July 6. The hearing was conducted by a special subcommittee, headed by Senator Claude Pepper, of the Senate Labor and Public Welfare Committee. Dr. H. A. Press, assistant to Chief Medical Director Paul B. Magnuson, informed the subcommittee there is no atomic or physiologic basis for chiropractic and pointed out that its dubious educational system stands in sharp contrast to the high professional training standards of medicine and osteopathy.

Testifying in support of the bill were Omar B. Ketchum, of Veterans of Foreign Wars; Charles Foster, of Disabled American Veterans, and John G. Nugent, of New Haven, Conn., representing National Chiropractic Association.

# Medical Legislation

## STATE LEGISLATION

### California

**Bills Introduced.**—H. Res. 237 proposes the creation of a commission to ascertain, study and analyze all facts relating to or in any way bearing on **public health** and to report back to the general assembly its recommendations for appropriate legislation. A. 3174 proposes an appropriation of $50,000 for research leading to the treatment and cure of **multiple sclerosis.**

**Bills Enacted.**—A. 771 has become chapter 546 of the Laws of 1949. It provides that no person, association or corporation shall maintain or conduct any institution, boarding home or other place for the reception or care of aged persons without a **written license** from the State Department of Social Welfare. A. 1954 has become chapter 722 of the Laws of 1949. It amends the Health and Safety Code **defining "biologics"** by including whole blood and blood derivatives and also preparations made from human as well as animal tissues or micro-organisms. S. 817 has become chapter 530 of the Laws of 1949. It amends the Business and Professions Code by providing, among other things, that nothing shall prohibit the board of medical examiners from disapproving any **foreign medical school** or from denying the application of such school if, in the opinion of the board, the instruction received by the applicant or the courses were not equivalent to that required in the California provisions relating to the licensing of physicians and surgeons.

### New Jersey

**Bill Enacted.**—A. 511 has become chapter 196 of the Laws of 1949. It authorizes a local board of health to quarantine any person afflicted with **tuberculosis of the lungs** in a communicable form, diagnosed as such by a licensed physician after examination by roentgenogram or finding of tubercle bacilli in the sputum or gastric washings, in order to protect others from becoming infected.

# Coming Medical Meetings

Aero Medical Association, New York, Aug. 29-Sept. 2. Dr. Thomas H. Sutherland, 214 S. State St., Marion, Ohio, Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va., The Homestead, Sept. 8-10. Dr. Leroy A. Calkins, University of Kansas Medical Center, Kansas City 3, Kan., Secretary.

American Congress of Physical Medicine, Cincinnati, Netherlands Plaza Hotel, Sept. 6-10. Dr. Richard Kovacs, 2 E. 88th St., New York 28, Secretary.

American Roentgen Ray Society, Cincinnati, Sept. 4-7. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Iowa, Secretary.

International Congress of Biochemistry, Cambridge, England, Aug. 19-25. Lt. Col. Francis J. Griffin, 56 Victoria St., London, W.C.1, Organizer.

Montana State Medical Association, Butte, Aug. 1-4. Dr. Herbert T. Caraway, 115 N. 28th St., Billings, Secretary.

Utah State Medical Association, Salt Lake City, Sept. 1-3. Dr. Ray T. Woolsey, 42 S. Fifth East St., Salt Lake City 2, Secretary.

Vermont State Medical Society, Burlington, Sept. 1-2. Dr. James P. Hammond, 542 Main St., Bennington, Secretary.

West Virginia State Medical Association, White Sulphur Springs, The Greenbrier, Aug. 4-6. Mr. Charles Lively, 1031 Quarrier St., Charleston, Executive Secretary.

# GOVERNMENT SERVICES

## ARMY

### BEGIN JOINT STAFFING OF NAVAL HOSPITALS

Joint staffing of four Naval hospitals with Army medical personnel at St. Alban's Hospital, Long Island, N. Y.; Corona and Long Beach hospitals, California, and Portsmouth Hospital, Portsmouth, Va., was announced July 1 by the Surgeon General. The joint staffing of military hospitals was recommended by the Hawley Board last January in order to economize on physicians and other scarce professional personnel and to reduce the number of hospitals. Under the plan, hospitals of the respective services allocate a certain number of beds for patients from other services. A total of 825 beds has thus been made available in these four hospitals for Army and Air Force patients.

Nine Army Medical Corps officers, including a pediatrician, an internist, a general surgeon, an orthopedic surgeon and five general duty physicians, are being assigned to St. Alban's Hospital, which has allocated 450 beds to Army and Air Force patients. Allocation of these beds made it possible for the Army to close Fort Totten General Hospital, Long Island, and to reduce Tilton General Hospital, Fort Dix., N. J., to station hospital status, effective June 30. Three Army Medical Corps officers in residency training have been assigned to Portsmouth Naval Hospital, which has allocated 100 beds to the Army and Air Force. At Corona and Long Beach hospitals, a total of 300 beds have been turned over to the Army and Air Force, making it possible to close McCormack General Hospital by June 30. An internist, a general surgeon and a general duty physician are being assigned to each of these hospitals by the Army Medical Department. Members of the Dental Corps, Army Nurse Corps, Medical Service Corps and Women's Specialist Corps and enlisted personnel are being assigned to these hospitals in proportionate numbers to help with the work load of all patients and augment the hospital staff.

In a similar joint staffing procedure, the Navy recently assigned personnel for duty at the Army's Tripler General Hospital at Honololul, Hawaii, where all Naval patients in the Philippine Island are now hospitalized.

### SELECT 486 NEW DOCTORS FOR INTERN TRAINING

The Surgeon General announced that a total of 486 medical school graduates and senior medical students were selected for the military intern and civilian intern programs and began their internships and training July 1. Commissions as first lieutenants in the Medical Corps Reserve have been given to 231 medical school graduates who were assigned to Army general hospitals taking part in the military intern program. These internships are offered each year to selected graduates of medical schools approved by the American Medical Association. Appointments begin on July 1 and terminate June 30 the following year. Commissions in the Regular Army are tendered to some at the close of the year. Twenty-four of those selected for the military intern program formerly held Reserve Corps rank in the Army, Navy or Air Force.

Selected for commissions as first lieutenants in the Medical Corps Reserve and assignment to civilian hospitals for intern training in the civilian intern program beginning July 1 are 255 medical school senior students. This program is designed primarily for young physicians who desire a career in the Regular Army Medical Corps. Applicants must have been accepted for internship training in a civilian hospital approved by the American Medical Association. Physicians selected for training under this program are required to serve two years on a duty status on completion of their year of intern training. During this year of training they are officers on active duty with full pay and allowances of the grade of first lieutenant.

### TRIPLER GENERAL HOSPITAL WELCOMES THE NAVY

The May 9 issue of *The Caducean,* which is published at Tripler General Hospital in Honolulu, is devoted largely to welcoming the Navy medical contingents and personnel to that new hospital in one phase of the unification of the medical service of the armed forces. When the transfer from the Aiea Naval Hospital is complete, the Navy will have on duty at the new Tripler Hospital, which heretofore has been exclusively an Army hospital, ten Navy medical officers, 35 Navy nurses, 125 Navy enlisted men; there will be about 300 Navy patients. Tripler thus becomes, in fact, the armed forces hospital for the Hawaiian area, serving personnel of the Army, Navy, Air Force, Marine Corps and Coast Guard; it will also care for island veterans and patients of the United States Public Health Service. The first Navy medical officer to be in charge of the Naval unit at Tripler is Captain Gordon Tayloe, M.C., whose distinguished career began when he enlisted in the Navy Hospital Corps in 1917. Following World War I, he went to Wake Forest College in North Carolina, then to the University of Maryland School of Medicine in Baltimore, where he graduated in 1937. Much of his service during World War II was in Central and Eastern China. Captain Tayloe organized the Medical Department for the Navy Corps in China, including twenty-four small medical dispensaries and three mobile field hospitals; for this service he was awarded the Legion of Merit.

### SELECTED FOR ADVANCED TRAINING

The following additional medical officers have been selected for advanced training in civilian institutions:

Colonel Arthur E. White, American Congress of Physical Medicine, Chicago, physical medicine

Colonel Harold B. Luscombe, American Congress of Physical Medicine, Chicago, physical medicine

Colonel Emmett M. Smith, American Congress of Physical Medicine, Chicago, physical medicine

Colonel Harold E. Coder, University of California, Berkeley, Calif., hospital administration

Lt. Colonel Frank W. Threadgill, University of California, Berkeley, Calif., hospital administration

Lt. Colonel James H. Gordon, University of California, Berkeley, Calif., public health

Lt. Colonel Lucio E. Catto, Philadelphia Psychoanalytic Institute, Philadelphia, psychoanalysis

Lt. Colonel James E. Tate, American Congress of Physical Medicine, Chicago, physical medicine

Lt. Colonel Clark B. Williams, American Congress of Physical Medicine, Chicago, physical medicine

Lt. Colonel John J. Marren, University of California, San Francisco, psychiatry and neurology

Major George W. Geiss, American Congress of Physical Medicine, Chicago, physical medicine

Major Joseph N. Schaeffer, American Congress of Physical Medicine, Chicago, physical medicine

Captain Donald W. S. Stiff, Massachusetts General Hospital, Boston, residency in radiology

Captain Irvine G. Jordan Jr., Tulane University Medical School, New Orleans, basic sciences, and Ochsner Clinic, New Orleans, orthopedic surgery

Captain Wayne R. Celhafen, American Congress of Physical Medicine, Chicago, physical medicine

Captain Edward J. Lorenze, American Congress of Physical Medicine, Chicago, physical medicine

Captain James S. Martin, American Congress of Physical Medicine, Chicago, physical medicine

First Lt. John H. Webb Jr., Grady Memorial Hospital, Atlanta, Ga., otorhinolaryngology

First Lt. Edward E. Mercier, Gallinger Municipal Hospital, Washington, D. C., residency in medicine, and Georgetown University Hospital, Washington, D. C., internal medicine

First Lt. David H. Nichols, Millard Fillmore Hospital, Buffalo, obstetrics and gynecology

First Lt. Paul Teplis, Grady Memorial Hospital, Atlanta, Ga., and Georgetown University Hospital, Washington, D. C., residency in medicine

First Lt. David C. Wilson Jr., University of Colorado, Denver, residency in psychiatry

First Lt. Frank J. Cozzetto, Colorado General Hospital, Denver, pediatrics

# PUBLIC HEALTH SERVICE

## THOROUGHGOING REORGANIZATION

A reorganization of the U. S. Public Health Service to permit the service to keep pace administratively with developments in the concept of public health, and with advances in public health practice resulting from progress in medical science, has been approved by Surgeon General Scheele. The changes, which bring the organization into closely knit groupings in the respective areas of Public Health Service responsibility were made after a year of study by a special committee on organization. In approving the new structural pattern, Dr. Scheele pointed out that it will enable the service to put forth its best efforts and will make possible more efficient management and direction of the programs authorized by Congress. The reorganization regroups the activities of the service within the framework of the four previously existing bureaus, so that closely related programs are brought together in a single overall administrative unit.

The four bureaus, which, in turn, are comprised of several divisions are: Office of the Surgeon General, Bureau of State Services, Bureau of Medical Services and the National Institutes of Health.

Under the reorganization, activities within the Office of the Surgeon General are limited to the over-all staff or advisory functions of the service. As presently constituted, the Office of the Surgeon General, under the direction of the Deputy Surgeon General, is composed of: Division of Commissioned Officers, Division of Public Health Methods, Office of International Health Relations, Office of Management Services, Office of Personnel, Office of Budget and Finance and Office of Purchase and Supply. The new structural plan brings together in the Bureau of State Services the federal-state and interstate programs of the service. Activities of the bureau are carried on in three branches: (1) Environmental Health Service, comprised of the divisions of Sanitary Engineering, Industrial Hygiene, Water Pollution Control, and the Environmental Health Center at Cincinnati; (2) Personal Health Service, consisting of the divisions of Chronic Disease, Dental Public Health, Tuberculosis, Venereal Disease, and the Communicable Disease Center at Atlanta; (3) Administrative and Staff Services, made up of the Division of State Grants, the National Office of Vital Statistics, and the Offices of Public Health Nursing, Health Education and Administrative Management.

### PERSONAL HEALTH SERVICES

New divisions in the Personal Health Services branch are the divisions of Chronic Disease, which brings together existing programs in these fields into one unit, and Public Dental Health.

Divisions just established or transferred to the Administrative and Staff Services branch of the Bureau of State Services are State Grants, which will coordinate programs of grants-in-aid to States, and the National Office of Vital Statistics.

### MEDICAL SERVICES

The Bureau of Medical Services is concerned with services directed toward remedying individual medical needs and is made up of programs of clinical care, evaluation of the nation's health resources and aid in the construction of hospital facilities.

To facilitate the effective performance of the bureau's functions, the divisions of Dentistry and of Nursing, previously in the Office of the Surgeon General, have been transferred to Medical Services. The Division of Hospital Facilities, which administers the national hospital construction program and which was previously in the Bureau of State Services, has been transferred to Medical Services. A new division, Hospital and Medical Resources, has been established in the bureau to strengthen studies and leadership in developing the medical resources of the nation.

The changes, which were made over a period of many months, were first effected in the National Institutes of Health, where reorganization was completed some time ago. The recently created Institute of Experimental Biology and Medicine and the Microbiological Institute resulted from the integration of several divisions and laboratories into coordinated units. The Mental Health Institute was established through the transfer to the National Institutes of the functions of the Division of Mental Hygiene, previously in the Bureau of Medical Services. Two additional institutes, the National Heart Institute and the Institute of Dental Research, have been established on authorization of the 80th Congress.

### NATIONAL INSTITUTE OF HEALTH

Components of the National Institutes of Health are: Office of the Director, Office of Scientific Reports, Office of Research Planning, Experimental Biology and Medicine Institute, Microbiological Institute, National Cancer Institute, National Heart Institute, National Institute of Dental Research, and National Mental Health Institute.

## REGULAR CORPS EXAMINATION FOR MEDICAL OFFICERS

A competitive examination for appointment of medical officers in the Regular Corps of the United States Public Health Service will be held on October 3-5. Applications must be received no later than September 5.

Appointments will be made in the grades of assistant surgeon (first lieutenant) and senior assistant surgeon (captain). Appointments are permanent in nature and provide opportunities to qualified physicians for a lifetime career in clinical medicine, research and public health. All commissioned officers are appointed to the general service and are subject to change of station.

For appointment in the grade of assistant surgeon, the applicant must be a citizen of the United States, at least 21 years of age and a graduate from a recognized school of medicine. Applicants for appointment in the grade of senior assistant surgeon, must meet the aforementioned requirements and must have had a total of at least ten years of educational training and professional experience subsequent to high school.

The professional written examination for the grade of assistant surgeon will cover the following subjects: (1) anatomy, physiology and biochemistry, (2) materia medica and therapeutics, (3) obstetrics and gynecology, (4) practice of surgery, (5) practice of medicine, (6) epidemiology and hygiene and (7) pathology and bacteriology. Senior assistant surgeon applicants will be examined on subjects 4, 5, 6 and 7, listed herein.

Examinations will be held at a number of points throughout the United States, located as centrally as possible in relation to the homes of candidates.

Entrance pay for an assistant surgeon with dependents is $5,011 per annum; for senior assistant surgeon with dependents, $5,689. These figures include the $1,200 annual additional pay received by medical officers as well as subsistence and rental allowance.

Application forms and additional information may be obtained by writing to the Surgeon General, United States Public Health Service, Washington 25, D. C. Attention: Division of Commissioned Officers. Complete applications must be received by Sept. 5, 1949.

## DR. KOLB RESIGNS

Dr. Lawrence Kolb has resigned as Director of Research Projects for the National Institute of Mental Health, and Dr. John Eberhart has been appointed to that position, effective July 1. Dr. Kolb has accepted a position as consultant in psychiatry at the Mayo Clinic, Rochester, Minn. Dr. Eberhart has been chief psychologist of the Training and Standards Branch of the National Institute of Mental Health. Prior to joining the Public Health Service Staff in 1947, he was chief of the Research Design Section, Surveys Division, Veterans Administration. He was formerly a member of the psychology faculty of Northwestern University and, for two years, was a post-doctoral fellow of the Social Science Research Council. He served as a Naval officer during the war. As Director of Research Projects, Dr. Eberhart will administer the program of grants in aid for research in the mental health field.

# Medical News

**(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)**

## CALIFORNIA

**Professor Fischer Wins Sugar Research Award.**—Prof. Hermann O. L. Fischer, Berkeley, carbohydrate chemist of the University of California, has been awarded the 1948 Sugar Research Award of $5,000. The National Academy of Sciences, which administers the award established by the Sugar Research Foundation, announced the selection. Professor Fischer came to Berkeley last year with Professor Wendell M. Stanley, chairman of the department of biochemistry and director of the Virus Laboratory. Dr. Fischer won the award on the basis of contributions to sugar and carbohydrate research, achieved mainly during his years at the Banting Institute at the University of Toronto. The award is the fourth annual Intermediate Prize presented by the foundation. Next year a $25,000 Grand Prize will be given for the outstanding research during the preceding five years, the Intermediate Prize winners being eligible.

## IDAHO

**State Medical Election.**—Idaho State Medical Association at its recent meeting in Sun Valley installed Dr. Walter R. West, Idaho Falls, as president and chose Drs. Russel T. Scott, Lewiston, president-elect and Alfred M. Popma, Boise, secretary-treasurer.

## ILLINOIS

**Personals.**—The Illinois Psychiatric Society at its election of officers in May chose Dr. Vladimer G. Urse, Chicago, as president and Dr. Louis D. Boshes, Chicago, secretary-treasurer. ——At the annual meeting of the Illinois Public Health Association in Chicago in April, Dr. Winston H. Tucker, commissioner of health of Evanston, was made president-elect of the Illinois Public Health Association.

### Chicago

**Research on Liver Diseases.**—The Board of Directors of the Hektoen Institute for Medical Research of the Cook County Hospital announces that the Dr. Jerome D. Solomon Memorial Research Foundation, an affiliate of the Hektoen Institute, has given its third annual grant of $12,300 for the continuation of research on diseases of the liver. This work is being done by Dr. Hans P. Popper, scientific director of the institute, and his associates.

**Gift for Laboratory to Study Allergy.**—Asthmatic Children's Aid has presented a gift of $10,000 to the University of Illinois Allergy Clinic to establish a histochemical laboratory for experiments in allergy. Asthmatic Children's Aid was organized in 1940 to further research on asthma and allergy and to provide relief for underprivileged children. The organization contributes also for the care of patients in clinics and the education of doctors who will specialize in the treatment of allergic diseases. The association has contributed a total of $50,000 to the University of Illinois in support of the Allergy Clinic.

## INDIANA

**Society Election.**—The Indiana Society of Anesthesiologists has elected Dr. Edward F. Bloemker, Indianapolis, president, and Dr. Richard E. Edmondson, Terre Haute, secretary-treasurer.

**Establish State Tumor Registry.**—The Indiana Association of Pathologists, in collaboration with the State Board of Health, the Indiana Cancer Society, the Indiana University School of Medicine and the Indiana State Medical Association, has established tumor registry for the statewide collection of data concerning all cases of cancer or cases suspected of being of cancer. The Indiana Cancer Society made this program possible by the provision of funds. The Indiana Association of Pathologists is giving assistance by studying the material as it is sent to the registry, while the Indiana State Board of Health is assisting by maintaining the registry under the direction of Dr. Wendell C. Anderson. About a year ago the Indiana Association of Pathologists, using funds provided by the Indiana Cancer Society, provided special training for a technician who now has headquarters in the department of pathology at Ball Memorial Hospital in Muncy. This technician is available on request for assistance in technical problems.

## KANSAS

**Program to Improve Rural Medical Care.**—A statewide program for improving rural medical care has been started by the University of Kansas School of Medicine, Lawrence, in cooperation with the Kansas State Medical Society and the Kansas Farm Bureau. Under the direction of Dr. Franklin Murphy, dean of the Kansas Medical School, Topeka, a program has been developed to (1) train more doctors with emphasis on the importance of general practice, (2) develop medical lectures and demonstrations for the country doctor in Kansas and offer more refresher courses for country doctors and (3) enlist the aid of communities to help recruit the doctors they need. The Kansas State Legislature has appropriated $3,800,000 for additions to the University of Kansas School of Medicine. The 72 Kansas communities which need doctors have public organizations or committees actively supporting a move to recruit doctors. Some communities are trying to attract doctors by offering to stake them for their beginning year; others offer facilities they need to practice medicine, and in most cases the townspeople provide buildings, equipment or loans without interest to make their communities more attractive.

## MAINE

**Jackson Memorial Laboratory Seminars.**—The first of the regular summer series of seminars at the Roscoe B. Jackson Memorial Laboratory, Bar Harbor, began June 30. The remaining program for the summer is as follows:

July 21, Mr. Eugene Roberts, St. Louis, Chemical Studies of Epidermal Carcinogenesis
July 28, Jackson Laboratory Genetics and Normal Growth Panel
August 1, Mr. Duncan J. McDonald, Hanover, N. H.
August 4, Mr. Garson H. Tishkoff, New York, Chromatographic and Microbiological Methods in the Study of Growth Factors
August 11, Jackson Laboratory Endocrines Panel
August 22, Mr. Philip White, Development of Tumors in Plants
August 29, Dr. David A. Karnofsky, New York, Studies on Chemotherapy
September 1, Jackson Laboratory Pathology Panel

The seminars which are open to all interested persons, are held at 7:30 p.m. at Aldersea in Bar Harbor.

## MASSACHUSETTS

**Personal.**—Dr. Francis C. Lowell, associate professor of medicine at Boston University School of Medicine, has been appointed assistant dean of the Harvard Medical School, Boston. Dr. Lowell is a graduate of Harvard Medical School, 1936.

**Dr. Hinton Promoted to Clinical Professor.**—Dr. William A. Hinton has been promoted to clinical professor of bacteriology and immunology in the Harvard Medical School, Boston. Dr. Hinton has been on the medical school staff more than 25 years. He is known especially for the Hinton test and the Davies-Hinton test for syphilis. Dr. Hinton was graduated from Harvard College in 1905 and from Harvard Medical School in 1912. After eight years of laboratory practice in the Boston Dispensary and the Massachusetts Department of Health Dr. Hinton joined the staff of the Harvard Medical School as an assistant in preventive medicine and hygiene in 1923. He also has been a lecturer at Simmons College since 1919.

## MISSOURI

**Army Colonel Named Medical School Dean.**—Lt. Col. Melvin A. Casberg, of the Surgical Consultants' Division, the Surgeon General's office, has been named dean of the St. Louis University School of Medicine, St. Louis, effective the latter part of July, after he is separated from the army. Colonel Casberg was graduated in 1936 from the medical school to which he will return as dean. In 1940 he went to India, where he was chief of the Umri Mission Hospital, Berar. In 1942 he returned to the United States, entered the army and saw service in the North African campaign. In 1943 Colonel Casberg was reassigned to the China-Burma-India Theater of Operations. In 1946 he entered private practice at Long Beach, Calif., and was chief of staff at Jones Clinic Hospital, Long Beach, and senior attending surgeon, Harbor General Hospital, Los Angeles County. He returned to active duty in the army in January 1949.

## NEW JERSEY

**New State Department Bureau.**—Dr. Geoffrey W. Esty, Westfield, assumed the duties June 1 of director of the newly created Bureau of Constructive Health. Dr. Esty, a graduate of Harvard Medical School, Boston, 1931, formerly practiced pediatrics in Westfield; in 1941 he became associated with the Bureau of Maternal and Child Health as supervisor of medical personnel; following service in World War II he rejoined the division as a full time pediatrician.

## NEW YORK

**Personal.**—Dr. John G. Sigsby, Albany, has accepted the position of medical director of the Aftosa Commission at México, D. F., Mexico. The association has been set up to improve the health of Mexican cattle. More than 500 American veterinarians and cattle handlers have volunteered in the program under the direction of the U. S. Public Health Service. Dr. Sigsby will serve as their physician.

**Teaching Day on Heart Disease.**—The Suffolk County Medical Society on July 27 will have the following program at the Central Islip State Hospital, beginning at 10:30 a. m.:

J. Hamilton Crawford, Brooklyn, Management of Acute Cardiovascular Emergencies
A. Wilbur Duryee, New York, Management of Peripheral Vascular Disease
William T. Foley, New York, Use of Anticoagulants in Cardiovascular Disease
Leon J. Warshaw, Flushing, Management of the Failing Heart

This instruction is provided by the Medical Society of the State of New York with the cooperation of the State Department of Health.

**Salmonella Centre.**—The State Health Department's Division of Laboratories and Research has been designated as a Regional Salmonella Centre to collaborate with the World Salmonella Centre at the State Serum Institute, Copenhagen, Denmark. The World Centre was established by authority of the World Health Organization last summer. Its objective is the collection and identification of Salmonella strains. The state department laboratory was one of the first American laboratories to collaborate with the State Serum Institute in Copenhagen before the second World War when an International Salmonella Centre, financed by the Commonwealth Fund, was established at the State Serum Institute.

### New York City

**Study of Premature Infant Mortality.**—The Child Health and Welfare Committee of the Medical Society of the County of Kings, in cooperation with the Maternity Newborn Division of the New York City Department of Health, plans to conduct an analysis of premature infant mortality in Brooklyn. A representative of the committee and of the health department will analyze the death certificates as well as the hospital records. At some future time it is planned to make the findings of this study available to the profession, and it is hoped that corrective action will be taken as a result of these findings. Dr. Henry Rascoff is chairman.

## PENNSYLVANIA

**Personal.**—The Hahnemann Medical College and Hospital of Philadelphia conferred an honorary degree of Doctor of Laws on Dr. Leroy E. Chapman, Warren, June 24. Dr. Champman also has received a certificate of life membership in the Temple University Alumni Association, awarded annually to a member of the University Alumni for outstanding service.

**Henry Phipps Institute.**—The University of Pennsylvania Committee on the Henry Phipps Institute has been reconstituted following the death of former President Thomas S. Gates and retirement of Drs. Charles J. Hatfield and Alfred N. Richards. George William McClelland, LL.D., chairman of the university, has replaced Dr. Hatfield as chairman of the committee; other members are as follows: Harold E. Stassen, president of the university; Paul Musser, LL.D., provost; William H. DuBarry, administrative vice president; Dr. Robin C. Buerki, vice president in charge of medical affairs; Orville H. Bullitt, trustee, chairman of the board of medical affairs, and S. F. Houston and Colonel Edwin M. Chance, trustees. The committee held its annual meeting in the Library of the Institute on May 30 and adopted the budget for 1949-1950.

### Philadelphia

**Society News.**—The Philadelphia Laryngological Society on May 3 elected Dr. Valentine M. Miller president, Dr. Harry P. Schenck treasurer and Dr. William J. Hitschler secretary. Dr. Chevalier L. Jackson was elected to the executive committee.

**Establish Nutrition Clinic.**—The Philadelphia General Hospital announces the establishment of a Nutrition Clinic, which, with its research laboratory, will study various nutritional problems among the patients in the hospital and school children in Philadelphia. Dr. Michael G. Wohl, associate professor of medicine at Temple University School of Medicine, will be chief of the clinic, and Katheryn Langwill, professor of nutrition at Drexel Institute, will act as nutritionist.

**Faculty Changes at Woman's Medical College.**—Dr. Isabelle H. Perry has resigned as director of the department of oncology of the Woman's Medical College and has been appointed full time executive secretary of the Subcommittee on Oncology of the Committee on Pathology for the National Research Council. Dr. Mildred C. Pfeiffer will become director of the department of oncology. Dr. Pfeiffer is a graduate of the University of Pennsylvania School of Medicine, 1936. She has been assistant director of oncology at the Woman's Medical College since 1948. Dr. Irene E. Maher, clinical instructor in medicine, is assistant dean, effective June 15. Dr. Maher was a graduate of the college in 1944.

## RHODE ISLAND

**State Medical Election.**—The Rhode Island Medical Society at its recent annual meeting installed Dr. Peter P. Chase, Providence, as president and chose Drs. Charles J. Ashworth, Providence, president-elect; Morgan Cutts, Providence, secretary, and G. Raymond Fox, Pawtucket, treasurer. Dr. Charles L. Farrell was elected delegate to the American Medical Association.

## WEST VIRGINIA

**New Medical Licensing Board.**—The new medical licensing board has succeeded to all licensing duties of the Public Health Council. Members appointed by the governor are: Drs. Walter E. Vest, Huntington, president since 1937 of the Public Health Council, for a four year term; William P. Bittinger, Summerlee, also a former council member, for a five year term. Others appointed by the governor as members of the new board are Dr. Cecil B. Pride, Morgantown, one year term; George F. Evans, Clarksburg, two years; Frank J. Holroyd of Princeton, three years, and Doff D. Daniel of Beckley, five years; chiropodists: D. A. Afflack, Parkersburg, two year term, and E. R. Johnson, Charleston, three year term; chiropractors: F. M. Remick, Wheeling, one year term, and R. E. Tripp, Fairmont, four year term. The new board was appointed under the provision of H. B. 134, passed by the legislature February 21. It held its first meeting July 7-9.

**State Medical Meeting.**—The annual meeting of the West Virginia State Medical Association will be held at the Greenbriar Hotel, White Sulphur Springs, August 4-6, under the presidency of Dr. Thomas G. Reed, Charleston. Guest speakers at the morning general sessions are as follows:

Lloyd H. Mousel, Washington, D. C., Newer Developments in Anesthesia
Maxwell Finland, Boston, Antibiotics
Harry Gold, New York, Recent Developments in Cardiac Drugs
Irving S. Wright, New York, Present Status of Anticoagulant Therapy in the Treatment of Thrombo-embolic Diseases
William D. Stroud, Philadelphia, Congestive Heart Failure
Michael E. DeBakey, Houston, Texas, Current Considerations of Peripheral Vascular Disease
Richard B. Cattell, Boston, Surgery of the Pancreas
Sidney Farber, Boston, Tumors in Childhood
Ralph M. LeComte, Washington, Significance of Hematuria
Bayard Carter, Durham, N. C., Carcinoma of the Cervix Uteri

Panel discussions will follow the sessions on Thursday and Friday, and a question and answer period is scheduled following the papers Saturday morning. Dr. Harold C. Lueth, Omaha, will speak Friday evening on "Medical Care in the Atomic Age." Guest speaker at the banquet Saturday evening will be Will Durant, whose subject will be "What Are the Lessons of History." The Woman's Auxiliary will meet in conjunction with the medical association.

## GENERAL

**National Medical Association.**—The annual convention of the National Medical Association will be held August 8-12 in Detroit, with headquarters at the Horace G. Rackham Educational Building. The program has been arranged by sections. Clinics will be held at Detroit hospitals.

**Fund for Research on Leukemia.**—The National Research Council announces the availability of a fund of $25,000 from the estate of Charles R. Blakely for support of research in the field of lymphatic leukemia. Applications for grants-in-aid from this fund are now being entertained. Application forms may be obtained from the Chairman, Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, N. W., Washington 25, D. C.

**Syphilis Case-Finding Campaign.**—More than 200 cities and counties in 28 states throughout the country are launching intensive syphilis case-finding campaigns during July and August. Approach to the public will be through material for use on the radio, on television, in movies and through advertising outlets purchased by state and local health departments. The U. S. Public Health Service has requested the assistance also of national magazines and other publicity channels.

**Special Society Awards.**—Dr. Herbert M. Evans, Berkeley, Calif., received the E. R. Squibb and Sons Award, and George Sayers, Ph.D., Salt Lake City, was named as the first recipient of the Ciba Award at the thirty-first annual meeting of the

Association for the Study of Internal Secretions held in Atlantic City June 3-4. It was also announced that Dr. Ernest M. Brown Jr., Philadelphia, has been selected as the Ayerst, McKenna and Harrison Fellow for 1949, and Dr. D. Lawrence Wilson is to be the Schering Fund Fellow.

**Heart Association New Research Grants.**—Eleven grants approximating $50,000 for investigation of heart and circulatory disease were announced June 27 by Dr. Harold M. Marvin of New Haven, Conn., president of the American Heart Association. New applications for Research Fellows and Established Investigators will be accepted up to September 15. Applications may be made to Dr. Charles A. R. Connor, Medical Director, 1775 Broadway, New York 19, N. Y. According to the American Heart Association, fellowships for established investigators will be ordinarily granted for a five year period, subject to annual review, for independent investigation at an annual stipend starting at $5,000 and with an annual increase of $500. These are open to superior persons of proved ability who are interested in a career in research. The research fellowships will be granted for one year, with stipends ranging from $3,000 to $4,000, and are open to graduates of approved medical or graduate schools who are interested in research and intend to follow an academic career.

**Prevalence of Poliomyelitis.**—Reports of cases of poliomyelitis for the periods indicated have been received from the Division of Public Health Methods, U. S. Public Health Service:

## PUERTO RICO

**Vaccinate Children Against Tuberculosis.**—More than 100,000 Puerto Rican school children will be vaccinated against tuberculosis during the next school year. This decision was reached at a meeting of federal and insular government officials, who met to discuss the use of BCG. Participating in the conference were insular commissioner of education Mariano Villaronga, health commissioner Juan A. Pons, Dr. Guillermo Arbona, of the insular health department, and Dr. Robert K. Williams, Robert J. Anderson and Dr. Edwardo Garrido Morales of the U. S. Public Health Service.

**New Medical School to Open in 1950.**—The rector of the University of Puerto Rico, Jamime Benitez, reports that the new school of medicine to be established in San Juan will start operation during the 1950-1951 school year. The school will be set up utilizing present facilities of the Postgraduate School of Tropical Medicine. The Superior Council of Education adopted a resolution to ask several medical professors on the staff of the School of Tropical Medicine who resigned their promotion soon after the law creating the new school was approved by the governor to continue in their posts. Dr. Enrique Koppisch is now acting director of the School of Medicine, and proper guarantees have been given to all employees of this institution that they will remain in their present positions. A resolution to that effect was adopted by the Superior Board of Education last month.

### Deaths in Foreign Countries

**Bernard E. Read, Ph.D.**, pharmacologist, acting director of the Henry Lester Medical Research Institute of Shanghai, China, died there June 13 after a long illness, aged 62. Dr. Read was a Rockefeller fellow at Johns Hopkins University, Baltimore, in 1916 and at Yale University, New Haven, Conn., in 1918. He served as professor of pharmacology at Peiping Union Medical College 1926-1932.——**Sir Frederick N. Menzies**, medical officer of health of the London County Council from 1909 until his retirement in 1939 and one of Britain's prominent physicians in the public health field, died May 15 at his home in London, aged 73.——**Professor Emilio Alfieri**, president Fondazione Mario Donati of Milan, Italy, died May 10. The foundation decided to commemorate the president by holding on June 16 the ceremony that he himself had planned for the official inauguration of the foundation.——**Sir James Purves-Stewart**, author of "Diagnosis of Nervous Diseases," which went into its ninth edition in 1945, and other publications, died in London June 15, aged 79.

## CORRECTION

**Dosage of Nor-Epinephrine.**—In the last column of table 2, in the article on nor-epinephrine in THE JOURNAL, July 2, 1949, page 777, the dosage of nor-epinephrine infused should have been expressed in micrograms per kilogram per minute instead of in milligrams.

**State Medical Election.** — The South Carolina Medical Association at its annual meeting installed Dr. Roderick MacDonald, Rock Hill, as president and chose Dr. Wilbur R. Tuten of Fairfax, president-elect; Dr. Julian P. Price, Florence, was reelected secretary-treasurer. The state medical election item in THE JOURNAL June 11, page 548, was in error.

# Marriages

HARVEY LORAINE BURNETTE JR., Cheraw, S. C., to Miss Mary Malissa Ratliff of Morven, N. C., June 4.

MORRIS JACOB SELIGMAN, Concord, N. H., to Miss Rhya Levine of Groton-on-Hudson, N. Y., in May.

JOHN EDWARD RYAN, Washington, D. C., to Miss Patricia Ellen Mortell of Oshkosh, Wis., April 23.

JOHN ALDEN VANN, Norfolk, Va., to Miss Anna Lyne Shackleford in Williamsburg, May 6.

MAURICE E. WILLIS, Burlington, Ky., to Dr. Lorraine Awes of Cedar Rapids, Iowa, May 24.

LEON J. SHULMAN, Los Angeles, to Miss Priscilla McIlvaine in Pasadena, Calif., May 27.

ROBERT F. NEAL, Carthage, Tenn., to Miss Caroline Acree Benz of Nashville, June 8.

J. TIMOTHY DONOVAN to Miss Eileen Frances McAllister, both of Brooklyn, in June.

## Deaths

**Thomas Addis,** San Francisco; born in Scotland in 1881; University of Edinburgh Faculty of Medicine, Scotland, 1905; in 1911 joined the faculty of Stanford University School of Medicine, where he had been professor of medicine and where in 1946 he retired from active teaching with the title of professor emeritus; fellow of the Royal College of Physicians of Edinburgh, which in 1942 awarded him the Cullen Prize "for the greatest benefit done to practical medicine in the previous four years"; member of the National Academy of Sciences, Association of American Physicians and the American Society for Clinical Investigation; fellow of the American College of Physicians; a former Carnegie Research scholar and fellow, and the first visiting scholar at the Long Island College of Medicine in Brooklyn, where in 1940 he delivered the Adam M. Miller Memorial Lecture; in 1931 he delivered the fourth course of lectures under the William Sydney Thayer and Susan Read Thayer Lectureship in Clinical Medicine, in the School of Hygiene and Public Health, Johns Hopkins University School of Medicine, Baltimore; co-author of "Renal Lesion in Bright's Disease"; author of "Glomerular Nephritis: Diagnosis and Treatment"; specialist certified by the American Board of Internal Medicine; died in Cedars of Lebanon Hospital, Los Angeles, June 4, aged 67.

**Roy Biggs Henline** ⊕ New York; born in Kearney, Neb., June 21, 1894; Northwestern University Medical School, Chicago, 1920; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the American College of Surgeons and the New York Academy of Medicine; member of the House of Delegates of the American Medical Association in 1943 and from 1945 through 1948; past president of the New York County Medical Society; served during World War I; on the staff of the Medical Arts Center Hospital; director of urology at Sydenham Hospital; consultant in urology at St. Luke's Hospital, Newburgh, Yonkers (N. Y.) General Hospital and Mount Vernon (N. Y.) Hospital; attending surgeon to the James Buchanan Brady Foundation at New York Hospital, where he died May 23, aged 54, of arteriosclerotic heart disease.

**John J. Sippy** ⊕ Stockton, Calif.; born in Venice, Ill., July 13, 1879; St. Louis College of Physicians and Surgeons, 1899; associate clinical professor of public health and preventive medicine, emeritus, Stanford University School of Medicine, San Francisco; past president of San Joaquin County Medical Society; member and past president of the American Public Health Association; formerly secretary of the Kansas State Health Officers Association; while practicing in Belle Plaine, Kan., served as part time public health officer of Sumner County; at one time epidemiologist for the Kansas State Health Department; formerly director of child welfare and epidemiologist for the Montana State Board of Health; died March 15, aged 69.

**Eli Herr Long,** Buffalo; born in Clarence, N. Y., July 24, 1860; University of Buffalo School of Medicine, 1882; joined the faculty of the University of Buffalo, where he became professor of materia medica and therapeutics and later professor emeritus, in the school of medicine, professor of materia medica in the school of pharmacy and professor of materia medica and therapeutics in the school of dentistry; member of the American Medical Association; past president of the Association of American Medical Colleges; for many years affiliated with the Buffalo General Hospital; author of four editions of Dental Materia Medica, Therapeutics and Prescription Writing and others; died May 31, aged 88.

**Clarence Franklin Ball,** Rutland, Vt.; born in 1878; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1902; past president of the Vermont State Medical Society; member of the American Medical Association; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society and the American Radium Society; fellow of the American College of Radiology and American College of Surgeons; founder of the Vermont Cancer Commission, of which he had been president; affiliated with Rutland Hospital, where he died May 15, aged 71, of embolism.

**James G. Douglass,** Ballinger, Texas; born in Covington Feb. 28, 1874; Medical Department of Tulane University of Louisiana, New Orleans, 1898; member of the American Medical Association; formerly secretary and president of Runnels County Medical Society and of the Fourth District Medical Society; served as city health officer, as local surgeon for the Missouri-Kansas-Texas Railway and the Santa Fe and Abilene Southern Railroad; formerly vice president of the First National Bank; died in a local hospital March 2, aged 75, of hypertension and cerebral hemorrhage.

**Karl Winfield Ney** ⊕ Stuart, Fla.; born in Franklin, Ind., Aug. 1, 1882; Louisville and Hospital Medical College, Louisville, Ky., 1908; formerly dean and professor of neurosurgery at the New York Polyclinic Medical School and Hospital and clinical professor of neurosurgery at the New York Medical College and Flower Hospital in New York; served overseas during World War I; at one time affiliated with the Presbyterian Hospital in New Orleans; formerly director of neurosurgery at the Neurological Institute of New York; died May 30, aged 66.

**John Adolph Bacher** ⊕ San Francisco; Harvard Medical School, Boston, 1911; Associate Fellow of the American Medical Association; clinical professor of surgery, emeritus (otorhinolaryngology), Stanford University School of Medicine; specialist certified by the American Board of Otolaryngology; formerly practiced in San Jose, Calif., where he was bacteriologist for the city board of health and secretary of Santa Clara County Medical Society; died April 10, aged 72, of carcinoma.

**Fred Daniel Baty,** Ruth, Nev.; University of Kansas School of Medicine, Kansas City, 1940; member of the Kansas Medical Society; died May 8, aged 42.

**Edgar Randolph Beckley,** Washington, D. C.; Howard University College of Medicine, Washington, 1897; died in Freedmen's Hospital May 19, aged 76.

**Karl Marx Bonoff** ⊕ Los Angeles; College of Physicians and Surgeons, Los Angeles, 1914; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society, Radiological Society of North America and the American College of Radiology; served during World War I; died May 10, aged 57, of injuries received in an automobile accident.

**William Benjamin Borden** ⊕ Colonel, U. S. Army, retired, Wayne, Pa.; University of Maryland School of Medicine, Baltimore, 1906; fellow of the American College of Surgeons; entered the medical corps of the U. S. Army as a first lieutenant in 1913; served during World War I; promoted through the various ranks to that of colonel on May 23, 1939; retired on Jan. 31, 1943, for disability in line of duty; died in Valley Forge General Hospital, Phoenixville, Pa., May 15, aged 69, of metastatic carcinoma.

**Jacob Harold Chalat** ⊕ Detroit; University of Michigan Medical School, Ann Arbor, 1917; served during World War I; charter member of the American Diabetes Association; died in Harper Hospital May 12, aged 61, of coronary sclerosis.

**Samuel Lee Cline,** Live Oak, Calif.; Kentucky School of Medicine, Louisville, 1908; died May 20, aged 76, of cerebral hemorrhage.

**David Leonard Cohen** ⊕ New York; University and Bellevue Hospital Medical College, New York, 1930; specialist certified by the American Board of Urology; served during World War II; on the staffs of the Montefiore and Beth Israel hospitals; died in Park East Hospital June 1, aged 47.

**Sidney Beeson Conger** ⊕ Wilmette, Ill.; Chicago College of Medicine and Surgery, 1914; served during World War I; died in Wesley Memorial Hospital, Chicago, May 29, aged 59, of carcinomatosis.

**Ernest Crockett,** Ashtabula, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900; served as county coroner; on the staff of Ashtabula General Hospital; died in Massillon May 18, aged 75, of arteriosclerosis.

**Avac Cutujian,** Frederick, Md.; Long Island College Hospital, Brooklyn, 1893; died in Frederick Memorial Hospital May 16, aged 88.

**Velpeau C. Dail,** Knoxville, Tenn.; Tennessee Medical College, Knoxville, 1891; member of the American Medical Association; died in Fort Sanders Hospital May 16, aged 77.

**John B. Dalton,** Graysville, Ga.; Atlanta College of Physicians and Surgeons, 1899; died April 23, aged 79.

**Don Favorite Deeter** ⊕ Troy, Ohio; University of Cincinnati College of Medicine, 1925; also a graduate in pharmacy; served during World War I; affiliated with Stouder Memorial Hospital, where he died May 20, aged 52, of coronary thrombosis.

**John E. Dusseldorf,** New York; Long Island College Hospital, Brooklyn, 1887; member of the American Medical Association; died May 23, aged 86.

**Homer Richard Evans,** San Bernardino, Calif.; California Eclectic Medical College, Los Angeles, 1913; served during World War I; died April 13, aged 67.

**Richard Fleischer** ⊕ New York; Friedrich-Alexanders-Universität Medizinische Fakultät, Erlangen, Bavaria, Germany, 1916; affiliated with the Beth Israel Hospital, Hospital for Joint Diseases and Mount Sinai Hospital, where he died May 8, aged 58.

**George William Funck,** Englewood, Fla.; Rush Medical College, Chicago, 1903; died May 19, aged 72.

**Walter Edward Futrelle,** Chillicothe, Ohio; Jefferson Medical College of Philadelphia, 1921; member of the American Psychiatric Association; served during World War I and II; since 1931 affiliated with the Veterans Administration; chief, professional services, Veterans Administration Hospital, where he died recently, aged 60, of coronary thrombosis.

**Walter Fitzgerald Hartman** ⊕ Richmond, Va.; University of Virginia Department of Medicine, Charlottesville, 1889; Bellevue Hospital Medical College, New York, 1890; an Associate Fellow of the American Medical Association; past president and secretary of the Augusta County Medical Society; served during World War I; died April 8, aged 84.

**John Martin Hayek,** Des Moines; State University of Iowa College of Medicine, Iowa City, 1926; member of the American Medical Association; for many years director of the division of maternal and child health, Iowa State Health Department; died in Iowa Methodist Hospital May 24, aged 47, of cerebral hemorrhage.

**Richard Gainsforth James,** Detroit; Detroit College of Medicine, 1904; member of the American Medical Association; served during World War I; died in Linden Beach, Ontario, Canada, May 29, aged 66.

**Malcolm Benjamin Jernberg,** Hollywood, Miss.; University of Louisville (Ky.) Medical Department, 1911; member of the American Medical Association; died in Methodist Hospital, Memphis, Tenn., May 18, aged 61.

**Thomas Robert Kennedy** ⊕ St. Louis; St. Louis University School of Medicine, 1919; on the staff of St. John's Hospital; died in the Mayo Clinic, Rochester, Minn., May 23, aged 51.

**Morris John Kotler** ⊕ San Diego, Calif.; Washington University School of Medicine, St. Louis, 1928; served during World War II; died May 23, aged 49.

**Edward Henry Krueger** ⊕ Denver; Bennett Medical College, Chicago, 1912; affiliated with St. Anthony's, Presbyterian and Samaritan hospitals; formerly member of the state athletic commission; died May 19, aged 60.

**Oran Robert Lasater** ⊕ Ballinger, Texas; University of Texas School of Medicine, Galveston, 1918; formerly secretary and president of the Runnels County Medical Society; served during World War I; died March 11, aged 60, of coronary embolism.

**William W. Lathrop,** Jackson, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; member of the American Medical Association; died May 7, aged 87.

**Anthony Joseph Manzella,** Buffalo; University of Buffalo School of Medicine, 1927; director of the division of communicable diseases, county health department; served as deputy city health commissioner and director of the division of communicable diseases for the city health department; died February 24, aged 48.

**Lovina Ruth Merritt Miller** ⊕ Sanitarium, Calif.; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1901; served on the staff of St. Helena Sanitarium and Hospital; died in April, aged 75.

**Louis Amandas Mueller,** Chicago; Rush Medical College, Chicago, 1899; died June 4, aged 75, of arteriosclerosis and paralysis agitans.

**Thomas J. Murray** ⊕ New London, Conn.; University of Maryland School of Medicine, Baltimore, 1910; past president of the New London County Medical Society; on the staff of Lawrence and Memorial Associated Hospitals; died April 16, aged 63, of hemorrhage from esophageal varices.

**Joseph Eugene Nelson,** Cambridge, Mass.; Jefferson Medical College of Philadelphia, 1945; certified by the National Board of Medical Examiners; associated with the Massachusetts Institute of Technology; killed May 22, aged 26, in an airplane crash near Pine Plains, N. Y.

**Charles Russell Nutt,** Plymouth, Wis.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; died in St. Nicholas Hospital, Sheboygan, March 31, aged 83, of chronic myocarditis and hypertrophy of the prostate.

**Romuald Othello Ostrowski** ⊕ Hammond, Ind.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; received the Silver Beaver award for his work with the Boy Scouts; died June 3, aged 68, of coronary thrombosis.

**Clara Fogle Palmer,** McAlester, Okla.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; died April 21, aged 76, of cancer of the gastrointestinal tract.

**Charles Burton Popplestone,** Fairfield, Me.; Dalhousie University Faculty of Medicine, Halifax, Nova Scotia, Canada, 1924; member of the American Medical Association; past president of the Knox County Medical Society; superintendent of the Central Maine Tuberculosis Sanatorium; killed March 30, aged 47, when his automobile was struck by a train.

**Henry Bradford Powell,** Ocean Springs, Miss.; Victoria University Medical Department, Coburg, Ontario, Canada, 1892; served in the Spanish-American War and World War I; died in Gulfport, May 30, aged 83.

**Karl Ferdinand Marius Sandberg,** Chicago; Kongelige Frederiks Universitet Medisinske Fakultet, Oslo, Norway, 1881; member of the American Medical Association; died June 4, aged 93, of coronary occlusion and chronic nephritis.

**William Dennis Scanlan,** Brooklyn; Long Island College Hospital, Brooklyn, 1907; member of the American Medical Association; on the staff of the Samaritan Hospital; died May 29, aged 68, of carcinoma of the stomach.

**Urban A. Schlueter** ⊕ Milwaukee; Milwaukee Medical College, 1912; member of the American Association of Industrial Physicians and Surgeons; past president and secretary of the Medical Society of Milwaukee County; formerly police surgeon; for many years on the staff of St. Luke's Hospital, where he died May 21, aged 59, of an internal hemorrhage.

**Gifford DeAlton Seitz,** Portland, Ore.; University of Oregon Medical School, Portland, 1932; member of the American Medical Association; specialist certified by the American Board of Obstetrics and Gynecology; clinical instructor of obstetrics and gynecology at his alma mater; on the staff of St. Vincent's Hospital; died May 27, aged 41, of coronary thrombosis.

**Mathew McKnight Shaw,** Madrid, Iowa; Drake University College of Medicine, Des Moines, 1904; member of the American Medical Association; past president of the Boone County Medical Society; died May 16, aged 73.

**John Joseph Shea,** New York; University of the City of New York Medical Department, 1891; died in St. Vincent's Hospital May 29, aged 81.

**Jacob Silver,** New York; Fordham University School of Medicine, New York, 1918; died in Boston recently, aged 55, of embolism.

**William J. Stribling,** Philadelphia, Miss.; Memphis (Tenn.) Hospital Medical College, 1900; for many years county health officer; director of the Citizens Bank; died May 24, aged 70.

**Glenn George Sweeley,** Hughson, Calif.; University of Southern California School of Medicine, Los Angeles, 1941; member of the American Medical Association; died May 25, aged 42.

**Archibald Moltz Wilkins** ⊕ Delta, Ohio; Toledo Medical College, 1898; past president of the Fulton County Medical Society; veteran of the Spanish-American War, Philippine Insurrection and World War I; on the staff of the DeEtte Harrison Detwiler Memorial Hospital, Wauseon; died March 29, aged 74, of coronary thrombosis.

## DIED WHILE IN MILITARY SERVICE

**Richard Ray Dalrymple,** Englewood, N. J.; Jefferson Medical College of Philadelphia, 1920; member of the American Medical Association and of the State Medical Society of Wisconsin; interned at St. Vincent's Hospital in Erie, Pa.; began active duty as a major in the medical corps, Army of the United States, on Sept. 1, 1942; died in the Walter Reed General Hospital, Washington, D. C., Oct. 19, 1947, aged 56, of tuberculosis.

**Alvin Jay Meyer,** New York; University of Pennsylvania School of Medicine, Philadelphia, 1945; interned at Lenox Hill Hospital; entered the medical corps, Army of the United States, with the rank of first lieutenant on April 25, 1946; promoted to captain; died in Honshu, Japan, Nov. 9, 1947, aged 25.

### Optokinetic Nystagmus

Dr. L. Cojazzi and Dr. O. Sala of Padua presented to the National Congress of Oto-Neuro-Ophthalmology an interesting report on the value of optokinetic nystagmus in the central vestibular syndromes.

Up to now some noteworthy results of a clinical character have been obtained in the course of physiologic and clinical investigations which have been carried out recently by the authors with regard to the difficult problem of the relationship interfering with the optokinetic and vestibular nystagmus induced in men in various conditions.

Starting from previous observations which confirmed constantly the fact that optokinetic nystagmus inhibits vestibular caloric nystagmus of opposite direction elicited with Weits' technic, the speakers have been able to demonstrate in a large series of patients these facts:

1. In persons who are normal from the oto-neuro-ophthalmologic point of view, a caloric stimulation, much more intense than that obtainable with Weits' technic, may induce a pronounced and prolonged nystagmus, which, however, may be inhibited always by a simultaneously provoked optokinetic nystagmus. For this phenomenon the term "peripheral, instrumental hyperreflexia" was coined.

2. Such inhibition on the part of the optokinetic nystagmus may be observed likewise in persons who present a pathologic peripheral hyperreflexia resulting from a "standard" caloric stimulus (method by Weits).

3. In patients, on the contrary, who presented a hyperreflexia on standard caloric stimulation of purely central origin through suffering of the supranuclear vestibular tracts, the optokinetic nystagmus was not of such degree as to inhibit the provoked nystagmus.

4. In some patients who presented spontaneous ocular nystagmus, the speakers studied the behavior of the optokinetic nystagmus with the aim to observe whether it might be possible to obtain a reliable element for differentiating the vestibular or extravestibular origin of a spontaneous nystagmus.

But in these cases the optokinetic nystagmus did not give constant results. Therefore the speakers stated that its behavior may not have an absolute differential value.

### Treatment of Gastroduodenal Ulcers

At the Second Interregional Congress of Medicine and Surgery held in Lecce, the problem of gastroduodenal ulcers was discussed extensively; three reports—one medical, one surgical and one roentgenologic—were presented.

The medical report was presented by Professor Di Guglielmo; after a rapid summary of the principal modern methods of medical treatment of ulcer disease, he established some fundamental concepts concerning uncomplicated ulcers as follows:

1. Although there does not exist at present a single specific cure, we have at our disposal a complex of therapeutic procedures by which one may succeed through various mechanisms to influence the numerous pathogenetic factors of gastroduodenal ulcers by suppressing or attenuating their noxious action.

2. Early diagnosis and perseverance in the application of hygienic, dietetic and pharmacologic norms lead to major successes with medical treatment.

3. Prevention of recurrences requires intervention in the prodromal phase, which may be manifested by neuromuscular symptoms several weeks before the reappearance of pain. The most important of these symptoms are fatigue, incapacity of concentration and bad mood in the early hours of the day; waking up at 3 or 4 o'clock in the morning represents an unusual fact in these persons who usually have slept normally and regularly. The neuromuscular symptoms subside with the administration of alkaloids of belladonna combined with phenobarbital (luminal®); in this stage of the disease the results of treatment are excellent.

4. Hormone treatment has not yet reached a point to yield therapeutic results, which could be expected on the basis of physiopathologic premises and experimental research.

5. Among the various methods of treatment actually practiced, some are based on the now indisputable physiologic concept that the vagus nerves are responsible for the excess in hyperacid gastric juice which may be observed in the empty stomach of patients with ulcer. Professor Di Guglielmo concluded that the facts reported by him represent the basis on which physicians and surgeons who in the past followed absolutely opposite routes, may meet one another in cooperative work which has as its aim to suppress the noxious action of the vagus nerves by medical and successively by surgical methods.

The surgical report was presented by Professor Palma who discussed the various methods of intervention for the surgical treatment of gastroduodenal ulcers. The speaker emphasized that one does not yet know well the effect of vagotomy on the function of the pancreas, liver, gallbladder, intestines, kidneys and adrenals. The possibility of aggravating the arterial hypertension has been mentioned. At present, with the exception of the cases of recurrence of ulcer, one cannot say that the results obtained with vagotomy are such that this method should be preferred to any other type of surgical treatment. Considering the multiple disturbances which had been observed in a certain percentage of cases, one would be rather induced to share the opinion of Deryl Hart's, who stated that from the functional point of view vagotomy may turn out to be more mutilating than resection and the resulting advantages may not compensate for the occasional complications.

Among the palliative interventions, in spite of today's wide use of resection, the gastroenterostomy has an incontestable place in the treatment of gastroduodenal ulcers, particularly in those cases in which, because of general and local conditions, a radical operation is not feasible.

Today extensive resection may be considered as the method of choice for surgical treatment of gastroduodenal ulcer. It is true that it does not correspond with the qualifications of causal therapy, but there is no doubt that by removal, in addition to the ulcerous focus, of a good part of the source of production of the acid secretion of the stomach it determines a state of achlorhydria, which is an undispensable condition for prevention of recurrences.

In discussing the medical treatment of perforated ulcer, the speaker emphasized that the experience is still too limited for definite judgment. Concerning surgical treatment, simple suture with omentopexy presents an intervention which is sufficient to save the life of the patient but does not present a remedy against occasional complications (hemorrhage, perforation). The resection, on the contrary, offers a remedy against perforation and at the same time a cure of the causal disease. The speaker does not recommend general performance of resection in all the cases of perforating ulcer, but he affirms that resection may yield excellent results in the hands of experts, when limited to patients of not too advanced age who are seen early (from the sixth to the ninth or at the most the twelfth hour after the perforation) and whose general condition is satisfactory.

Hemorrhagic ulcer formed the last subject dealt with by the speaker. As long as there is only moderate hemorrhage, it does not impair the efficiency of the organism and may be compensated for by the protein hematic reserves of the organism. In these cases, particularly if the condition occurs for the first time in young persons and in persons without previous gastric disturbances, medical treatment should be practiced.

On the contrary, when one has to deal with patients over 40 years, with previous gastric disturbances for many years, with evacuation of blood and in whom considerable hemorrhages recur, precocious intervention seems advisable, which will give better results than that performed in a later period when toxic factors may be associated with the anemia thus increasing the operative risk.

The roentgenologic report was presented by Dr. Calabrese who used many roentgenograms in discussing the development and the structural consequences of gastroduodenal ulcer.

### Treatment of Liver Disease with Lipotropic Substances

At the Medical Society of Naples Dr. F. Cutillo reported the results obtained by him in 8 cases of diseases of the liver treated for fifteen days with the pancreatic antifatty liver factor prepared according to the technic of Entenman, Montgomery and Chaikoff.

In addition to the usual tests of hepatic function, the protein content was ascertained every five days during the entire duration of the treatment and five days after treatment was discontinued.

The level of protein proved to be an optimum test of hepatic function, and in those cases in which restoration of the protein values to normal has been verified the therapeutic results from use of the antifatty liver factor were definitely verifiable in the clinical manifestations as well as in the other functional tests. In cases in which the protein values remained unchanged, there were no other signs of improvement.

The speaker closed his report by emphasizing that the data of the protein picture maintain all their value as an expression of hepatic function when the liver is compromised clinically and that in some cases the restoration or the lack of restoration of the protein ratio to normal may represent a prognostic sign of great usefulness.

### Denmark's Infant Mortality

The outer world seems to think that we Scandinavians are one big family with much the same medical problems and achievements whether the country in question is Denmark, Norway or Sweden. To be sure, we all have a high public health standard, and our vital statistics are a source of gratification to ourselves and, we modestly hope, a source of inspiration to our neighbors. But when we take stock of ourselves in some detail, we find from time to time that progress in medicine has not been equally effective in these three countries. Infant mortality illustrates this point rather well. In 1947 the infant mortality in Denmark was 4 per cent, whereas in Sweden it was only 2.5 per cent. In other words, Sweden could share with New Zealand the claim to being the country with the lowest infant mortality in the world, while Denmark had to concede pride of place in this respect to such countries as Holland, Switzerland and Norway. Substantial consolation is, however, to be found in the fact that Denmark's infant mortality was as high as 13.4 per cent as recently as 1901. Since then there has been a rather jerky fall; in the period 1920-1930 there was hardly any fall whatever. The fall since 1901 has largely been due to a higher standard of living and, of late years, to a more effective treatment of bronchopneumonia. When BCG vaccination has become fully established we may expect a further fall owing to the elimination of the score of deaths still due to tuberculosis in infancy every year.

But how can we indulge in any self complacency as long as our own infant mortality is so much higher than that of Sweden? Dr. P. Hertz of Copenhagen has recently discussed this problem. His most important point turns on breast feeding, which is practiced much more conscientiously in Sweden. Another of his points is that infant welfare as a discipline has been given much greater prominence in Sweden, where pediatrics has been a subject for the examination of medical students since 1845. In Denmark, on the other hand, it was not till 1939 that this subject was allowed to rank as high as medicine and surgery in the medical curriculum. In this respect Norway has held an intermediate position, having adopted pediatrics as an independent discipline in 1893.

### The Wassermann Testing of Pregnant Women

The law of Oct. 1, 1945 (no. 472), concerned with the hygiene of pregnancy, provided for the routine Wassermann testing of the blood early in pregnancy. Now, with a perspective of some three years, it is possible to take stock of this measure and to form an approximate estimate of its effectiveness. It is probable that about 80 per cent of all the pregnant women in Denmark are now given the benefits of this test. But to what extent is it undertaken early enough in pregnancy to be an effective guide to the prevention of congenital syphilis? Dr. P. Wiingaard has lately published the results of an inquiry into this matter undertaken by the State Serum Institute in Copenhagen, to which all blood samples are sent. The inquiry showed that at the beginning of the fifth month of pregnancy only 55.7 per cent of the samples had been taken. The remaining 44.3 per cent were taken during or after the fifth month of pregnancy. In as high a proportion as 17.1 per cent (corresponding to 12,000 pregnancies yearly) the samples were not taken till the seventh, eighth or ninth month of pregnancy. At so late a stage of pregnancy the prospects of preventing congenital syphilis, based on a positive Wassermann reaction, are meager. Dr. Wiingaard suggests that a well sustained educational campaign is the best measure for reform in this field. The prospects for it are the brighter for the fact that Danish expectant mothers have shown themselves intelligently appreciative of the benefits conferred on them by the new law.

### Every Third Patient a Mental Case?

We have of late got into the way of saying with axiomatic pedantry that in general practice every third patient is more or less a mental case. But what carefully analyzed statistical investigations exist in support of this claim? The Danish psychiatrist, Dr. H. I. Schou, who is in charge of the Dianalund Hospital, has lately set out to verify this claim by securing the cooperation of eight medical practitioners in Odense. They have undertaken to keep a record during 1949 of all their patients with regard to the part played by the mental or psychic factor. They have promised to keep special records of their cases of neurasthenia "nervosismus," neurosis, hysteria, mental depression and psychopathia. They note (1) whether these conditions constitute the main or a side issue, (2) the duration of the treatment received under ambulant conditions as well as of unemployment, (3) the cost of drugs and loss of earnings and (4) the relative number of such patients according as they are or are not given resident treatment in a hospital.

Realizing that this local investigation may be insufficient for his purpose, and that conditions are not the same in town and country and that the interest a doctor takes in psychiatry may greatly affect the composition of his sick list, Dr. Schou has issued an appeal to doctors all over Denmark to join in this scheme of research for a year. It is hoped by this means to check the accuracy of the statement that there are at present 150,000 cases of neurosis in Denmark. Dr. Schou has already sought to ascertain the number of patients receiving hospital treatment and pecuniary compensation for neuroses in 1944 and 1946, and his findings will shortly be published. If he can secure sufficient cooperation in his scheme for the investigation of the amount of ambulant treatment devoted to neuroses, we should have a fairly complete picture of both the ambulant and the hospital treatment of mental patients in Denmark.

## MEDICAL PRACTICE IN TURKEY

*To the Editor:*—Recently I spent a vacation investigating the present state of medical practice in Turkey. Having spent several years there (1902-1909) at which time native civilian medical practice was deplorably lacking in both quality and quantity, I wished to learn whether the amazing transformation of the social, educational and cultural life of the people, following in the wake of the revolution in the early 1920's was also apparent in their medical practice, hospitals and sanitation.

In general, I found that to be the case. Such physicians as Dr. Beçet Uz, ex-minister of Turkey's Department of Health, Dr. Kadri Olçar and Dr. Sürreyeh Görduren, all of Ankara, the capital, are physicians of a high order of excellence devoted to their profession and generous of their time and courtesy to the visitor. Dr. Görduren is an internationally known ophthalmologist and is on the corresponding editorial staff of the *British Journal of Ophthalmology,* as I learned from several reprints which, at my request, he gave me. His office equipment included all that one could desire, of German, English and American manufacture.

He has somewhat of a preference for intracapsular cataract extraction and showed me several cases, also a case of anthrax of the eye. Anthrax is not uncommon in Turkey and, I was told, responds well to penicillin therapy. Trachoma is plentiful but less so than formerly because of better sanitation. Formerly a large proportion of the population was afflicted by it and most cases of blindness were due to it. The university I found modern and interesting. The archeologic collections of Hittite origin are probably unrivaled anywhere, which is to be expected, for Ankara is near the center of that ancient kingdom.

At Erzerum I found Dr. Rivki, head of the local health department, cordial and tireless in showing me his hospital and equipment. In addition to the civilian there is also a new military hospital, modern in appearance, befitting the military importance of the city.

Returning by plane to Istanbul, I found it more difficult to contact the faculty members of the medical school, as it was closed for vacation; but I met Dr. Neçit Ferit, formerly professor of chemistry and found he has been much in America and has a perfect and idiomatic command of English. His present activities include chemical manufacturing, a field of development much needed in Turkey, especially in the realm of medicine.

Turning to foreign hospitals, which for the most part are American, one may mention as the two largest the one in Aintab (now Gaziantep) established by Dr. Shepard the elder, and that more recently started by his son, Dr. Lorrin Shepard in Istanbul. The latter is known as the Admiral Bristol Hospital—a tribute to him personally who was greatly esteemed by Turks and Americans alike in Istanbul. It is also commonly called the American hospital.

In addition to medical, surgical and special wards, there is a nurses' training school. Housing for the nurses and student nurses is inadequate, and a financial campaign for a building for them is under way. As planned it will cost nearly $150,000 and would meet the needs of that part of the hospital for many years. I was shown the hospital thoroughly by Dr. Shepard and was most favorably impressed by it and by the way it is conducted. As to be expected both the Doctor and his institution go at peak capacity. He is a member of the Istanbul medical society and participates in its activities as occasion permits. Professionally he keeps well up to date.

City and rural sanitation I found still imperfect, but much progress has been made; I no longer encountered, as I did years ago, midstreet open sewers, food in the shops black with flies, universal trachoma and pavements sometimes festooned with *Ascaris lumbricoides.* Nor did I deem it necessary to flame the native bread with an alcohol lamp before eating it as I did in the interior of Turkey years ago. Apparently the populace still distrusts the watermains for drinking purposes to some degree, for bottled drinking water is everywhere in evidence and is paid for as a matter of course. Typhoid is not everywhere and always, as formerly; but it is not rare as in America. The same can be said of malaria.

Sulfonamide drugs and penicillin are well known and in general use. In Ankara and Istanbul the health department doctors are making good use of descriptive and illustrated charts of infectious diseases placed in small "museums of hygiene" in parks and pleasure resorts.

H. L. UNDERWOOD, M.D., Portland, Ore.

## ACUTE ARTERIAL INJURIES

*To the Editor:*—Although the lateness of the hour barred my attempted discussion of Dr. Freeman's paper on "Acute Arterial Injuries" (THE JOURNAL, April 23, p. 1125), the alleged injury of tissues by refrigeration and especially Dr. de Takats' assertion that refrigerated tissues cannot survive should still be compared with the following facts: (1) the survival of animals' legs after fifty-four hours (my original experiments) and of rats' tails after ninety-six hours (Brooks and Duncan) of refrigeration without circulation; (2) the healing of stumps after the usual refrigeration with a tourniquet for several hours, extended in one instance to forty-eight hours (Crossman); (3) the successful reconstruction of a mangled hand after packing in ice for two weeks (Nachlas); (4) severed fingers, hanging only by a shred of skin, saved with refrigeration for several days when they could not be saved otherwise (Crossman, Kanaar and others); (5) reduced temperatures for orthopedic treatments (Schaubel) and refrigeration anesthesia without a tourniquet for orthopedic operations (Gratz); (6) Kross's saving of both life and limb in a badly infected burn of a leg by several days of radical refrigeration and eleven weeks of more moderate cooling; (7) the practical value of refrigeration in arterial wounds, demonstrated by: (*a*) refrigeration of legs for two or two and one-half weeks (Mock) or one month (Ottaway and Foote) after severance or thrombosis of femoral or iliac arteries, with successful subsequent amputation above the knee—i. e., far down within the refrigerated region; (*b*) suggestive indications that amputations for arterial occlusion below the knee might sometimes be avoided by sufficiently prompt use of refrigeration (Bowers); (*c*) Blakemore's successful restoration of dogs' legs after amputation and storage in an ice box for twenty-four hours, suggesting that cleanly severed human limbs or those with only the arteries destroyed may be thus preserved for perhaps several days during transportation to a suitably equipped hospital. Elsewhere I shall discuss further the misconceptions which have resisted the weight of facts and which, together with technical faults, explain why refrigeration has not yet been properly appreciated and used in a single large surgical clinic. Particular stress should be placed on the unique ability of cold to control simultaneously pain, shock, infection and tissue devitalization in various major traumatisms, on the saving of more tissue in burns than by any other treatment and on similar benefits in limb embolisms, including an unprecedented lengthening of the time limits for successful embolectomy.

FREDERICK M. ALLEN, M.D., New York.

*To the Editor:*—Dr. Frederick M. Allen's great contribution toward the proper management of suddenly or gradually devitalized limbs lies in his insistence on the deleterious effects of increased temperatures on the viability of ischemic extremities.

Daily one encounters heat cradles, hot water bottles and electric pads applied after occlusion of arterial circulation. These measures accelerate gangrene and often necessitate amputation which could have been avoided.

It is also true that the ischemic, pregangrenous or frankly gangrenous extremity, when packed in ice, will become painless; absorption from such extremities is slowed or interrupted, as evidenced by the drop in the patient's temperature. As pointed out in my discussion, this is a valuable procedure, allowing the surgeon time to control the patient's diabetic status, his depletion of blood or electrolytes. Where I thoroughly disagree with Dr. Allen is in his advocacy of using refrigeration as anesthesia for amputation and for maintaining refrigeration around extremities which may still be viable.

My discussion of course was of Dr. Freeman's paper and not of Dr. Allen's method of refrigeration. Dr. Allen has repeatedly and forcefully expressed himself on the subject and marshalled the evidence contained in his present letter. Part of the evidence is not germane to the present discussion, since it is sufficiently known that well vascularized organs or parts may be kept for many hours or days in suspended animation with a depressed metabolism and decreased oxygen requirement. Even here the increased capillary permeability and plasma exudation following the termination of the exposure to cold produces the immersion limb syndrome, the deleterious late effects of which are sufficiently known. The immersion limb with its neuropathy, its muscle and connective tissue fibrosis, its vasomotor changes, represents one of the most intractable sequelae to prolonged exposure to cold. The affected soldiers and sailors had no previous impairment of circulation.

When we are dealing, however, with ischemic extremities, which was the topic of discussion, the vascular and nerve damage is obviously of increased severity. Dr. Allen quotes the experiments of Brooks and Duncan, whose conclusions really pointed to a deterioration of viability when the refrigeration was removed. He has ignored the studies of Large and Heinbecker and Bruneau and Heinbecker (*Ann. Surg.* 120: 707-715, 715-726, 726-741 [Nov.] 1944), who showed that refrigeration delays wound healing and decreases the power of resistance of tissues to bacterial invasion. In the dog, after cooling to 6 C. the subcutaneous tissue failed to show the inflammatory response usually elicited by inoculation with hemolytic streptococci; however, after cooling had been stopped, definite harmful effects were noted. Also during the cooling period, there was no reaction on the part of the tissues to the trauma of an incision and subsequently there was a definite lag in wound healing. Finally, nerve degeneration was obvious in limbs of the experimental animal cooled at 6 C. for ninety-six hours. Their careful experimental and clinical observations should definitely serve as a warning against the use of chilling as a procedure for anesthesia. Adding the tourniquet to the chilling, which seems part of the procedure, is also objectionable, not only from the standpoint of circulation but because of the danger of tourniquet paralysis. You only have to have one tourniquet paralysis never to forget it.

There is nothing simpler than to wrap an ischemic extremity in cotton from toes to midthigh, maintaining body temperature and preventing heat loss by evaporation. It is quite possible that special apparatus, delivering an environment of 60 to 65 F., might be occasionally useful. But the chilling of the extremity to 40 F. (5 C.), which Dr. Allen has postulated in his writings and defended with such vigor and skill, is definitely injurious when applied for several hours and days to an ischemic extremity; such extremities may have survived this injury due to chilling not because of it, but in spite of it.

Geza de Takats, M.D., Chicago.

## EXPERIMENTAL FEEDING OF PROTEINS

*To the Editor:*—In the editorial on Nutritive Value of Proteins in the January 29 issue of The Journal, page 311, experiments are cited in which intact proteins were supplemented with a free amino acid (cysteine).

At the American Medical Association Convention, in Atlantic City in June 1947, Dr. Paul Cannon described experiments on the utilization of a solution of a biologically adequate mixture of amino acids. When one of the essential amino acids was removed from the mixture and given one, two or four hours subsequent to administration of the balance of the mixture, utilization was impaired and negative nitrogen balance occurred. Dr. Cannon concluded that amino acids are available for utilization for not more than an hour or two after their introduction into the blood stream.

An abstract (Kuiken, K. A., Lyman, C. M.: Availability of Amino Acids in Some Foods, *J. Nutrition* **36**: 359 [Sept.] 1948) which appeared in the January 22 issue of The Journal, page 260, emphasizes this point more strongly: "The ultimate synthesis of body protein from the amino acids made available through digestion and absorption is dependent on a third factor, namely, the simultaneous appearance in the blood stream of each of the essential amino acids in suitable proportions. Protein synthesis does not occur unless a complete mixture of the essential amino acids is present at one time."

Free amino acids are crystalloids, and abundant evidence attests to the fact that they are absorbed from the gastrointestinal tract at a rate comparable to that of dextrose.

When cysteine is fed with an intact protein, it may well be expected that it will be absorbed and largely deaminated several hours before completion of the absorption of the amino acid released on digestion of the protein.

Would it not appear that the foregoing factors should be given adequate consideration (1) in conducting tests of the nature described by Dr. Hess and his associates, and (2) in arriving at conclusions from such tests in which adequate provision is not made to assure simultaneous availability of all of the amino acids fed?

John F. Seward, Ph.G., Detroit.

## ESSENTIAL HYPERTENSION

*To the Editor:*—In discussing the article by Wilkins, Freis and Stanton, "Essential Hypertension" (J. A. M. A. 140: 261-265 [May 21] 1949) Dr. S. K. Robinson quotes me as saying, "Ninety per cent of essential hypertension is of nonrenal origin." In the presentation referred to before the Section on Pathology and Physiology at the annual meeting of the American Medical Association in June 1948, I stated that approximately 10 per cent of persons with essential hypertension succumb to renal failure (malignant hypertension). I further emphasized that essential hypertension is probably a generic classification and that current research on pathogenesis points to neurogenic, renal and endocrine factors, each of which may ultimately delineate a future, separate species of hypertension.

Contrary to Dr. Robinson's belief, "there will not be much progress in hypertension as long as one has the idea that a primary disease like hypertension can be produced by a vegetative organ like the kidney," I believe that some of the most significant recent progress in our understanding of hypertension has been stimulated by the concept that a renal mechanism may be operative in essential hypertension. The numerous similarities between experimental renal (Goldblatt) hypertension and essential hypertension as seen in many patients do not necessarily indicate even a partial common pathogenesis but are suggestive of this possibility. Moreover, present research by others and by our group on the pathogenesis and treatment of experimental renal hypertension will lead to a therapy worthy of trial in essential hypertension. Such therapy will afford evidence supporting renal pathogenesis in any patients responding favorably under carefully controlled conditions. When this therapy is available, I predict that some patients will be benefited in a manner similar to the excellent responses seen in our renal hypertensive dogs, but whether these patients will constitute 10 per cent, 30 per cent or more of patients with essential hypertension remains to be determined.

George E. Wakerlin, M.D., Chicago.

# Council on Medical Education and Hospitals

## NEW HOSPITALS REGISTERED

*The following hospitals were registered by the Council on* Medical Education and Hospitals of the American Medical Association at its meeting in Atlantic City, June 4, 1949:

Barber Hospital, Butler, Ala.
Chickasaw Infirmary, Chickasaw, Ala.
Hamil Clinic-Hospital, Decatur, Ala.
Blake Manasco Hospital, Haleyville, Ala.
Shelby Clinic-Hospital, Wilsonville, Ala.
Grand Canyon Hospital, Grand Canyon, Ariz.
El Sereno Lodge Sanitarium, Phoenix, Ariz.
Reid-Barnett Hospital, Arkadelphia, Ark.
Verser Clinic-Hospital, Harrisburg, Ark.
Harris Hospital and Clinic, Newport, Ark.
Corcoran Municipal Hospital, Corcoran, Calif.
Long Beach General Hospital, Long Beach, Calif.
Accadia Sanitarium-Hospital, Los Angeles
Midway Hospital, Los Angeles
Rose-Netta Hospital, Los Angeles
Children's Convalescent Hospital, San Diego, Calif.
Tracy Community Memorial Hospital, Tracy, Calif.
Glenwood Springs Hospital, Glenwood Springs, Colo.
Wyndover Hospital, Stamford, Conn.
Hernando County Hospital, Brooksville, Fla.
Kissimmee Hospital, Kissimmee, Fla.
Page and Fowler Private Hospital, Orlando, Fla.
Memorial Hospital, Panama City, Fla.
Municipal Hospital, Port St. Joe, Fla.
Hutchins Memorial Hospital, Buford, Ga.
Chamblee Hospital, Chamblee, Ga.
Arrendale Hospital, Cornelia, Ga.
Heard County Memorial Hospital, Franklin, Ga.
Atkinson Memorial Hospital, Woodbine, Ga.
Hazlecrest *General Hospital*, Hazlecrest, Ill.
Maple Lane Nursing Home, Macomb, Ill.
Jefferson County Hospital, Mount Vernon, Ill.
Mahoney Convalescent Home, Peoria, Ill.
Xavier Hospital, Dubuque, Iowa
Hovenden Memorial Hospital, Laurens, Iowa
Kingman Memorial Hospital, Kingman, Kan.
Dechairo Hospital, Westmoreland, Kan.
Rosary Hospital, Campbellville, Ky.
Our Lady of Mercy Hospital, Owensboro, Ky.
Prestonsburg General Hospital, West Prestonsburg, Ky.
Jones-McConnell Clinic-Hospital, Bunkie, La.
Clinton Infirmary, Clinton, La.
Caldwell Hospital and Clinic, Columbia, La.
Douglas Clinic and Hospital, De Quincy, La.
Sandifer Sanitarium, Logansport, La.
Legion Memorial Hospital, Newellton, La.
Everett-Biggs Clinic Hospital, Oak Grove, La.
*Ardoin Sanitarium, Ville Platte, La.*
Children's Hospital, Hagerstown, Md.
Cranbrook Infirmary, Bloomfield Hills, Mich.
Hynds Convalescent Hospital, Flint, Mich.
Mason General Hospital, Mason, Mich.
*Hart Hospital, Monticello, Minn.*
Riverview Memorial Hospital, St. Paul
Leonard Wright Sanatorium, Byhalia, Miss.
North Mississippi Hospital, Holly Springs, Miss.
Masonite Hospital, Laurel, Miss.
Leland City Hospital, Leland, Miss.
Atwood Hospital, Carrollton, Mo.
Doctors Hospital, Poplar Bluff, Mo.
Liberty County Hospital, Chester, Mont.
Community Memorial Hospital, Sidney, Mont.
John B. Simons Hospital, Whitefish, Mont.
Thayer County Memorial Hospital, Hebron, Neb.
Wakefield Community Hospital, Wakefield, Neb.
Warren Hospital, Phillipsburg, N.J.
Espanola Hospital, Espanola, New Mexico
St. Ann's Hospital, Hot Springs, N. Mex.
Lehman Hospital, Portales, N. Mex.
Bensonhurst Nursing Home, Brooklyn
*Corinth Hospital, Corinth, N. Y.*
Horace Harding Hospital, Elmhurst, N. Y.
Brookhaven National Laboratory Hospital, Upton, L. I., N. Y.
State Hospital, Butner, N. C.

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. Sept. 12-14. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc. *Oral.* Denver, Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

American Board of Internal Medicine: *Written.* Oct. 17. Asst. Sec.-Treas. Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Obstetrics and Gynecology, Inc. *Part I.* Various Centers. Feb. 3. Final date for filing application is Nov. 5. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Ophthalmology: St. Louis, Oct. 15-19; Boston, December. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery. *Part II,* New York City, Feb. 9-10. Final date for filing application for Part II is Aug. 15. Address: Sec.-Treas., Dr. Harold A. Sofield, Room 1856, 122 S. Michigan Ave., Chicago.

American Board of Otolaryngology: Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Chicago, Oct. 7-8. Final date for filing application is Sept. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: *Oral.* Cleveland, Sept. 16-18; New *York City, Oct. 21-23; Chicago, Dec. 9-11. Sec., Dr. John* McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Preventive Medicine and Public Health: *Parts I and II.* New York, Oct. 22-24. Final date for filing application is July 22. Sec., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore.

American Board of Psychiatry and Neurology, Inc. *Special Examination,* Chicago, Oct. 24-25. December, New York City. Final date for filing applications is Sept. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Cincinnati, Sept. 28-Oct. 2. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, October 26. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: *Written,* December. *Oral and Clinical.* Chicago, Feb. 11-15. Final date for receipt of case histories is Sept. 1, 1949. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18.

### BOARDS OF MEDICAL EXAMINERS

ALASKA: * Juneau, Sept. 6. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

DISTRICT OF COLUMBIA: * *Examination.* Washington, Nov. 14-15. Sec., Dr. G. C. Ruhland, 4130 E. Municipal Bldg., Washington.

GUAM: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O., San Francisco.

MONTANA: Helena, Oct. 3-5. Sec., Dr. Otto G. Klein, First National Bank Bldg., Helena.

NEVADA: Carson City, Nov. 7. Sec., Dr. George H. Ross, 112 N. Curry St., Carson City.

NEW HAMPSHIRE: Concord, Sept. 8-9. Sec., Dr. J. S. Wheeler, 107 State House, Concord.

NEW MEXICO: * Santa Fe. Oct. 10-11. Sec., Dr. Charles J. McGoey, Coronado Bldg., Santa Fe.

PENNSYLVANIA: *Examination.* Philadelphia and Pittsburgh, July. Acting Sec., Mrs. B. G. Steiner, 351 Education Bldg., Harrisburg.

PUERTO RICO: San Juan, Sept. 6-10. Sec., Dr. Luis Cueto Coll, Box 3717, Santurce.

SOUTH DAKOTA: * *Examination.* Pierre, July 19. Sec., Dr. G. J. Van Heuvelen, Capitol Bldg., Pierre.

WASHINGTON: * Seattle, July 18-20. Sec., Mr. Edward C. Dohm, Department of Licenses, Olympia.

* Basic Science Certificate required.

### BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: Juneau, Aug. 28. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

ARKANSAS: *Examination.* Little Rock, Oct. 4. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

DISTRICT OF COLUMBIA: Washington, Oct. 24-25. Sec., Dr. G. C. Ruhland, 4130 E. Municipal Bldg., Washington.

FLORIDA: *Examination.* Gainesville, Nov. 5. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

MICHIGAN: *Examination.* Detroit and Ann Arbor, Oct. 14-15. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing 15.

NEBRASKA: Omaha, Oct. 4-5. Director, Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln 9.

OREGON: Portland, Sept. 10 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

RHODE ISLAND: *Examination.* Providence, Aug. 10. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

WISCONSIN: Milwaukee, Sept. 24 and Dec 3. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Bureau of Legal Medicine and Legislation

## MEDICOLEGAL ABSTRACTS

**Malpractice: Death Following Administration of Chloroform.**—The plaintiff filed suit for damages for the death of her 7 year old daughter alleged to have resulted from the malpractice of the defendant physician. From a judgment in favor of the physician, the plaintiff appealed to the court of appeal of Louisiana.

The plaintiff's daughter was playing with some other children during the afternoon recess of the Franklinton School, and, as a result of being pushed by one of the children, she fell and broke her right arm. The principal of the school made an attempt to locate the child's mother by calling places where she worked, and, being unable to locate her, he then telephoned the defendant physician who told him to bring the child to his office. The principal testified that he felt the child needed medical attention at once, and, after attempting to locate the mother and failing, he thought it best to get the child to a doctor as soon as possible. Although the plaintiff lived only a mile from the school, he made no attempt to locate her at home as he did not know whether he would find her there and he "was most interested in getting the little girl to a physician as quickly as possible in order that her wrist might be set." He was accompanied to the defendant's office by Miss Thelma Wood, another teacher, who remained with the child during the entire operation and until after she died.

The law seems to be well settled, said the court of appeal, "That where the physician or surgeon uses all the customary precautions practiced by the profession in the particular locality, no liability is incurred. Thus, the highest degree of skill and knowledge is not required in every case, but only such skill and knowledge and practices as are common with the profession in the locality where the physician or surgeon happens to practice." The court of appeal then quoted from an opinion by Judge Taft, then of the United States Circuit Court of Appeals, in the case of *Ewing v. Goode*, 78 F. 442, in which Judge Taft said: "A physician is not a warrantor of cures. If the maxim 'res ipsa loquitur' were applicable to a case like this, and a failure to cure were held to be evidence, however slight, of negligence on the part of the physician or surgeon causing the bad result, few would be courageous enough to practice the healing art, for they would have to assume financial liability for nearly all the 'ills that flesh is heir to.' . . . The rule is well established that a physician or dentist cannot be held liable for the death of a patient under his treatment, where there is no evidence to show negligence or lack of skill on his part, sufficient to overcome the prima facie case in his favor made by the evidence that the treatment adopted by him was the usual and customary one. The fact that a patient died in such circumstances does not raise any presumption of negligence or lack of skill on his part." From this statement of the law, the Louisiana court continued, it is necessary to examine the record to ascertain whether or not the defendant was guilty of malpractice in failing to make a proper examination of the child before placing her under the anesthetic, in giving or causing to be given an overdose of chloroform, or in failing to obtain the consent of the mother before undertaking the treatment of the child.

The defendant testified that after determining the kind and nature of the fracture, he decided that he would use chloroform in setting the arm. Before giving chloroform, he always examines the heart of the patient, and in this instance, he said, he examined this child's heart by determining the size as near as possible, the rate of the pulse, the character of the pulse and listening to (termed "auscultation") the heart with a stethoscope. He also listened to the lungs for any pathosis that might be present. The physician and surgeon at the Elizabeth Sullivan Memorial Hospital in Bogolusa testified that prior to giving an anesthetic to anyone he would ascertain how the heart was functioning; that is, he would listen to see whether the heart was functioning normally, to determine whether there was any tuberculosis or cold that might be aggravated by an inhalation type of anesthesia, and that he would make this examination with a stethoscope. That is exactly the same examination made by the defendant before administering the anesthetic to the child in this case, said the court, and there was no testimony in the record that any different examination was ever made by any other physician in that parish or neighborhood. Therefore the defendant was not guilty of malpractice on that count.

As to the second charge, that the chloroform was administered by an incompetent assistant and the child was given an overdose, the court continued, the record revealed that with the facts and circumstances in this case chloroform was the recognized anesthetic to be given by the doctors in the surrounding countryside. The defendant's office was heated by an open-face gas heater, and it was agreed by all medical witnesses that ether could not be used around an open flame as it is very highly inflammable and, in such circumstances, might cause an explosion of the patient's lungs. Two other physicians testified that chloroform was the proper anesthetic to use with the facts in this case and that, in the same circumstances, they would have used it also. This testimony sustains the defendant in his choice of the use of chloroform. Mrs. Sweeney, the defendant's office nurse, testified that she administered the anesthetic. She had trained in a hospital for twenty-six months and only lacked ten months of finishing what would have entitled her to a certificate as a registered nurse. She had been giving the anesthetic for the defendant in his practice ever since she was employed by him in 1933. In our opinion, the court of appeal concluded, the testimony showed that she was well versed in the administration of anesthetics and the effect of the same and the different stages involved in general anesthesia. She was competent to give the chloroform in the present case, and, furthermore, she administered it under the direction of the defendant who was present at the time she gave it.

The plaintiff testified that the child's nose, face and mouth were burned and that the chloroform was given direct from the bottle and that there was no mask used. This testimony, however, was entirely refuted by the defendant, his nurse, Miss Wood, the teacher who remained with the child until her death, the coroner, the undertaker and his assistant who embalmed the child, and Miss Stringfield, another teacher in the grade school who saw the child after she died. The testimony showed that the chloroform was given by the drip method. A regular mask with gauze on it was placed over the patient's face and the chloroform dropped on this gauze.

The defendant and his nurse both testified that the child went from the first stage of anesthesia, which is shown to be "before you induce sleep," directly to the last stage, which is death. Another physician testified that some patients are hypersensitive to certain anesthetics and that there is no way of determining this prior to application. There is no doubt from the testimony in this case, continued the court, that the plaintiff's daughter was hypersensitive to chloroform, which produced an immediate toxic condition resulting in her death and which was diagnosed by the coroner as chloroform poisoning. When chloroform is well diluted with air and the patient dies, it is with respiratory failure first and cardiac failure later or within several minutes, due to the lack of oxygen. When chloroform is administered too quickly and in too large amounts, so that it is not well diluted with air, the heart stops beating first. In the instant case, there was respiratory failure first and the heart was beating for several minutes afterward. It is apparent, therefore, that this child did not die from an overdose of chloroform but as a result of a toxic condition produced by the chloroform.

The plaintiff next charged that the defendant did not endeavor to resuscitate the child. Miss Wood and the defendant's nurse testified that artificial respiration was used as well as hypodermics, and the defendant testified that he "immediately began trying to revive the child by means of injections of epinephrine into the vein and giving artificial respiration because the heart was still beating, but the child was not breathing. This did not work so I gave a hypodermic of 1/130 grain (0.5 mg.) of atropine sulfate. Then I continued to give artificial respiration in the usual manner—I think by three different methods: lying prone with rhythmic pressure and releasing the lower ribs posteriorly and working the arms back and forth to and from the body; putting the child over my shoulder and taking her back; these methods failed and I then gave the child an injection of coramine® (nikethamide); still no breathing, the child's heart was getting weaker. I injected 0.5 cc., I am not positive about the amount, it could have been 1 cc., into the heart muscles." There is no doubt from the testimony, concluded the court of appeal, that everything was done to revive the child.

Finally, there remains to be decided the question of whether the defendant is liable by reason of the fact that he failed to obtain the consent of the mother, who was a widow, before undertaking the treatment. "The general rule that a surgeon operates at his peril without first obtaining the consent of his patient or someone legally authorized to consent for him is qualified in its application by most courts in cases of emergency or unanticipated conditions where some immediate action is found necessary for the preservation of the life or health of the patient, and it is impracticable to first obtain consent to the operation or treatment which the surgeon deems to be immediately necessary. . . . In such a case, where the emergency endangers the life or health of the patient, it is the surgeon's duty to do that which the case demands within the usual and customary practice among physicians and surgeons in the same or similar localities, without the consent of the patient or his parents." (41 American Jurisprudence 222.) In this case, the court pointed out, the principal called the canning plant where he understood the mother was working and Dr. T. C. W. Magee's office, in an effort to locate her before he called the defendant. We are of the opinion that an emergency existed and that in such emergency the defendant was fully justified to proceed in the manner in which he did without the express consent of the child's mother. The defendant followed the usual and customary practice among physicians and surgeons in the same locality.

The judgment of the trial court in favor of the defendant physician was accordingly affirmed.—*Wells v. McGehee, 39 So. (2d) 196 (La., 1949).*

# Medical Motion Pictures

## FILM REVIEWS

**An Improved Technic for the Operative Treatment of Anorectal Lesions.** —16 mm., silent, color, 1,200 feet (1 reel or 3 reels), showing time forty-four minutes. Prepared in 1947-1948 by Louis E. Moon, M.D., F.A.C.S., Associate Professor of Surgery, Head of Department of Proctology, and J. B. Christensen, M.D., B.S., Instructor in Surgery, Associate in Department of Proctology, Creighton University School of Medicine, with the assistance of William H. Hardman, M.D., M.S., Creighton Memorial St. Joseph's Hospital, Omaha. Produced by Merrin W. LaRue, Inc., Chicago, through a grant by and procurable on loan from the William S. Merrell Company, Lockland Station, Cincinnati 15.

This motion picture presents the principles of physical diagnosis in anorectal inflammatory disease, the underlying pathogenesis and the proper surgical management of these conditions, especially the more common ones such as hemorrhoids, anal fissures, anal abscesses and fistulas.

Reel I deals with the proctologic examination. The anatomy of the region is clearly depicted by animated illustrations. Patients are used in demonstrating some of the more common pathologic conditions.

Reel II gives the essential points necessary for surgery, namely; (*a*) adequate facilities and qualified personnel, (*b*) preparation and position of patient and (*c*) anesthesia to produce anal relaxation, thus assuring adequate exposure of the operative area. It portrays the author's procedure for removal of internal and external hemorrhoids.

Reel III illustrates the surgical indication and management for anal fissures, abscesses and fistulas. The advantages of the technics are summarized at the end of each operative procedure.

Of excellent teaching value is the correlation of anorectal anatomy, pathogenesis of anorectal inflammatory disease and the surgical management of the various types of such disease. The stress laid on the importance of postoperative care is also well brought out in this film.

The use of fistulectomy rather than fistulotomy is disappointing for the reason that fistulotomy is considered adequate in the management of an anal fistula and is a much safer procedure especially in the hands of the less experienced surgeon. From a teaching point of view, it would have been much better to demonstrate the fistulous tract from its primary to its secondary opening, rather than vice versa as shown in the film.

In spite of these few exceptions and criticisms, this excellent production is suitable for showing to state and county medical meetings, residents, interns and fourth year medical students.

The photography and drawings are excellent throughout the entire film.

**The Vaginal and Cervical Smear.** A prebiopsy aid toward the early detection of carcinoma. 16 mm., silent, color, 1,025 feet (1 reel), showing time thirty minutes. Prepared in 1948 by Clair E. Folsome, M.D., F.A.C.S., under the guidance of George N. Papanicolaou, Ph.D., M.D., Cornell University Medical College, New York. Procurable on loan from Ortho Research Foundation, Graphic Arts Division, Raritan, N. J.

This film portrays the interpretation of cytologic appearances in smears obtained in cancer of the cervix and uterus and in a variety of conditions which may have to be considered in the differential diagnosis. Reproductions of normal structures including schematic drawings and reproductions of histologic preparations and of smears are illustrated, together with gross pictures of the normal cervix and of benign lesions. The technic of preparation of smears is shown only casually.

The reproduction of gross views of cancerous lesions and of some of the smears leaves much to be desired. The white and deep purple colors present an unnatural appearance.

The majority of scenes are still pictures, and one has the impression that a series of lantern slides or filmstrips would better serve the purpose. The photomicrographs of the cervix are poor to good.

The term "malignancy" is used throughout, whereas "cancer" is the more appropriate designation.

This film can be recommended for orientation of the gynecologists and medical students as an introduction to the much discussed topic of prebiopsy by means of study of desquamated cells.

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Treatment of Severe Singultus. F. G. Barnard.—p. 230.
Reduction of Mortality in Intestinal Obstruction. W. R. Moses.—p. 235.

**Strangulated Femoral Hernia.**—Jarboe and Pratt observed that the viscera most often incarcerated in strangulated femoral hernias were portions of small intestine and omentum. The relationship of the contents of the hernial sac to the fatality rate reveals that in 64 of the 104 cases parts of the small intestine were found in the hernial sac and that 23, or 36 per cent, of these 64 patients died, whereas of the 40 patients in whom viscera other than the small intestine were lodged in the femoral ring only 1 died (2.5 per cent). Extremely high fatality rate was associated with the presence of gangrenous portions of small intestine in the hernial sac. There were 19 deaths among the 26 patients in whom the strangulated segment of the small intestine was gangrenous, or a fatality rate for this group of 73.1 per cent. The contents of the hernial sac found in 104 strangulated femoral hernias indicate a definite relationship between the origin and pathologic condition of the affected viscera and the fatality rate. In cases of strangulation of parts of the small intestine, when surgery has been delayed and irreversible pathologic changes have taken place, the prognosis is very grave for a person of any age. Since physical resistance in the aged is materially lowered, such persons are benefited most by early surgical treatment, but the prognosis is influenced more by the condition of the strangulated viscera than by the factor of age alone.

**Modification of Bankhart Capsulorrhaphy.**—Luckey points out that the numerous modifications of the Bankhart procedures that have been described in recent years advocate either a new instrument to make the necessary holes in the glenoidal rim or various forms of internal fixation of the capsule, such as tacks, screws and staples. The author has used tacks, but the eventual fate of these tacks is still unknown and a patient may attribute residual postoperative distress to these radio-opaque objects. For these reasons the author has resorted to the use of the "pull-out" wire as described by Bunnell. The author describes and illustrates the technic he uses, but claims no originality. He has used the "pull-out" wire in 15 cases and has never observed infection following its use. At first small caliber wire was used, but in 1 patient the wire had broken off posteriorly just below the skin. That portion of the wire that held the capsule in contact with the scapula had not moved, so the final result was not impaired. Since that time, heavier wire has been used, usually no. 26, or, when this is not available, no. 24.

**Treatment of Severe Singultus.**—Barnard points out that persistent hiccup may threaten life, particularly when it complicates surgical interventions. When conservative measures fail, surgical treatment, usually bilateral phrenectomy, is resorted to. However, the crushing or resection of the phrenic nerve is a serious procedure and leaves the elderly patient in a handicapped state. The author shows that hiccup may be relieved by the application of two small sponge electrodes to the proper sites of the affected patient and the administration of pulsating galvanic sinusoidal current at a comfortable tolerance of 20 to 30 pulsations per minute. This produces stimulation of the phrenic nerve and contracts the diaphragm. The exact modus operandi by which the hiccup is stopped is not clear, but apparently the impulses running to the diaphragm are interrupted and probably the muscle itself is tired as a result of the galvanic stimulation. The author describes the technic of this treatment and presents 5 cases to illustrate the simplicity of technic and its potentialities. While some patients may not respond to this simple therapeutic aid, the results obtained have been uniformly excellent and merit further investigation.

Infectious Polyneuritis. N. S. Stearns.—p. 325.
Prolonged Auricular Tachycardia: Report of Case Persisting for 132 Days. E. K. Doak.—p. 338.
Advances in Treatment in Neurologic Diseases. A. Silverstein.—p. 344.
Metastatic Tumors of Central Nervous System. G. Wilson and C. Rupp.—p. 350.
*Importance of Sodium Intake in Management of Cardiac Failure. M. Sokolow.—p. 353.
Functional Uterine Bleeding. J. A. Hepp.—p. 361.
Newer Forms of Cutaneous Therapy. W. E. Wooldridge, H. L. Joseph and R. S. Weiss.—p. 363.
Nature and Function of Emotions, a Concept. S. H. Tyler.—p. 368.

**Sodium Intake in Cardiac Failure.**—Sokolow reports 3 patients, 2 women aged 49 and 47, respectively, and 1 man aged 52, with symptoms and signs suggesting congestive heart failure. The first patient was desperately ill with severe orthopnea, cyanosis, ascites, alternating pulse and gallop rhythm. In view of her previous episodes of cardiac failure the prognosis appeared poor. The tremendous loss of fluid within three days of beginning a salt-free diet and the rapid restoration to essentially normal cardiac function which resulted were striking. In the second female patient with a long-standing history of hypertension, the absence of cardiac enlargement, the essentially normal electrocardiogram and the presence of a normal venous pressure cast considerable doubt on the diagnosis of congestive heart failure. Dietary study revealed a high intake of sodium. By reducing the sodium in her diet, the patient became free of all symptoms, continued to be ambulatory and was able to increase her activities. In the third patient long hours of erect posture combined with excessive salt intake produced peripheral edema simulating congestive heart failure. Correctly interpreted and treated by the limitation of salt, the edema and dyspnea completely cleared and the patient was enabled to work again full time at his usual occupation without symptoms. Not all cases of cardiac failure require the radical restriction of sodium in the diet to 350 mg. which is in use at the University of California Hospital. If the cardiac failure is slight and the cardiac reserve is good, modest restriction of the sodium intake will usually suffice. In severe cardiac failure the patient may be unable to excrete even small amounts of sodium and the sodium intake must be drastically reduced. If the patient has both renal insufficiency and cardiac failure, a diet low in sodium may be dangerous and increased care and judgment are required to determine the amount of salt which will be best for both functions.

### American Review of Tuberculosis, New York

Comparison of Immunogenicity for Guinea Pigs of BCG Cultured Intermittently and Continuously in Presence of Bile. I. S. Neiman and Nelda Holmgren.—p. 102.

**Decortication in Pulmonary Tuberculosis.** — O'Rourke and his co-workers say that the results obtained during the war with the decortication of the lung in the management of organizing hemothorax suggested that this technic could be applied successfully in certain tuberculous patients. This study is concerned with 43 cases of pulmonary and pleural tuberculosis in which decortication was between January 1946 and May 1948. Observations on these cases demonstrated the presence of a "peel" similar to the organized exudate found encasing the lung in organizing hemothorax. Decortication has been restricted to the complications of tuberculous pleurisy in 9 patients and the complications of the therapeutic pneumothorax in 27 patients. In addition, decortication was done in conjunction with a lobectomy in 7 patients. The success or failure to remove a "peel" does not seem to be related to the duration of the pneumothorax but rather to the amount of the peripheral pulmonary disease. Twenty-eight lungs were completely decorticated and in 15 a partial decortication was performed. Streptomycin was not available at the beginning of this study, but since becoming more plentiful has been used routinely. The results of decortication in the 43 patients have been classified as: failure, 4; improved, 5; good, 14, and excellent, 20. The present status of the patients is as follows: 31 at home, 11 in hospital and 1 dead.

**Myanesin® as a Muscle Relaxant.**—Griffith and his associates discuss the muscle-relaxing properties of myanesin® (3-ortho-toloxy-1,2-propanediol). They conclude that the drug is fairly effective when administered in the recommended dosage, but that occasional local irritation at the site of injection and the occurrence of hemoglobinuria make its continued clinical use inadvisable. It has no advantage over curare in anesthesia.

**Suprascapular Nerve Block in Shoulder Pain.**—Rovenstine in 1941 introduced with Wertheim the technic of blocking the suprascapular nerve at the lesser scapular notch. The desirability of establishing the block at this point was its accessibility and the fact that no branches from this nerve are given off to the shoulder before it passes through the lesser scapular notch. Suprascapular nerve block was advocated as an adjunct in the treatment of chronic shoulder pain. Milowsky and Rovenstine report on 100 consecutive, unselected patients with shoulder pain; the greatest number was admitted with the diagnosis of bursitis. A good result was obtained in both the acute and chronic variety in the majority of patients following one block. Three patients with bursitis were not benefited by the suprascapular block. The mode of action of this treatment is not completely understood, but vasodilation might play a part. This would encourage vascularization and facilitate absorption of calcium deposits. Several patients have demonstrated in a follow-up examination roentgenologic evidence of loss of calcium. A second possibility is that relief of pain permits motion which, in turn, improves vascularization. The effects of suprascapular nerve block on pain of osteoarthritic origin were not uniformly successful. Patients with "idiopathic shoulder pain" experienced alleviation of symptoms following suprascapular nerve block. Supraspinatus and capsular tears may be effectively treated by nerve block if the injury is not complete or massive.

**House Ivy Dermatitis.**—Rynes points out that house ivy has been cited in rare instances as a cause of dermatitis. A patient, aged 51, had a summer rash for seven or eight years. The attacks occurred in bouts, lasting three or four days with several exacerbations during the summer months. On one occasion, after having cut down some house ivy and trampled it into a basket, he had an extensive dermatitis of the hands and feet, which necessitated confinement to bed for several days. The diagnosis of dermatitis venenata due to house ivy was suspected and confirmed by patch test. Leaves were desiccated and broken up, and 10 Gm. were immersed in 100 cc. of absolute alcohol for twenty-four hours and then filtered through dry paper. A patch test with the undiluted extract was strongly positive. Prophylactic treatment was begun in May with 0.25 cc. of a 1 : 1,000 dilution of the alcoholic extract. The amount of extract required was drawn into a dry tuberculin syringe. To this was added sufficient buffered saline solution to make a volume of 0.3 to 0.4 cc., and the syringe was rapidly inverted two or three times. The active principle of the alcoholic extract was thrown out of solution into a finely divided suspension. This suspension was immediately injected deeply into the subcutaneous tissue of the arm. The prophylactic injections were continued at intervals of four to seven days until a level of 0.2 cc. of a 1 : 10 dilution was reached in five weeks. The maximum dose was repeated in July and again in August. The patient remained free of his usual summer rash. The author feels that a similar approach can be employed in other cases of dermatitis venenata in which a plant sensitivity is suspected. A preliminary patch test should be made with a leaf of the suspected plant, and if this proves positive, an alcoholic extract can be prepared within twenty-four to forty-eight hours.

**Comparative Time Action of Globin Insulins.**—Rohr and Colwell studied the time action of standard globin insulin and compared it with ordinary insulin and with protamine zinc insulin. Comparisons were made by obtaining many blood sugar curves and urinary sugar curves showing the action of single doses of the same size in well stabilized patients with diabetes mellitus. The possibility of altering the characteristic time action of globin insulin by varying its globin content was also investigated by the same method of comparison. In diabetes mellitus of moderate severity, the following characteristics of 60 unit doses of various globin insulin mixtures in comparison with other insulin preparations were demonstrated. Standard globin insulin has a time action which is fairly rapid, showing initial effect within four hours. Its maximum effect is apparent in the concentration of blood sugar in eight to sixteen hours and in that of urine sugar in eight to twenty hours. This effect persists into the second day after the injection is made. Its action is intermediate between that of ordinary insulin in solution and that of protamine zinc insulin. A mixture of equal parts of regular insulin and standard globin insulin has an accelerated and shortened action. It is intermediate between its two components in this respect. Increasing the globin content of standard globin insulin from 3.8 to 38.0 mg. per hundred units of insulin does not appreciably alter its time action. Although these investigations were made chiefly from a pharmacologic point of view, certain therapeutic applications became obvious. In situations characterized by postprandial glycosuria or nocturnal hypoglycemia or both, when protamine zinc insulin is used in large dosage, globin insulin is certainly indicated. Whether it will give as good control in such situations as protamine zinc insulin mixtures will be decided by the method of trial and error. In daily morning injections, it will give a more intense daytime insulin effect and wear off more rapidly than protamine zinc insulin but still permit some degree of overlapping from day to day in doses of 60 units. Acid or clear globin zinc insulin cannot be modified by addition of more globin for the purpose of prolonging its activity or making it less intense. If such modification is desired, suitable mixtures of insulin and protamine zinc insulin should be used. If increased promptness of action is desired, globin insulin can be supplemented by admixture with ordinary insulin in proportions up to about equal parts. Such mixtures might be useful for patients who tend to show nocturnal hypoglycemia and glycosuria after meals on globin insulin.

**Myenteric Plexus in Congenital Megacolon.**—Whitehouse and Kernohan feel that one approach to the study of the origin and pathogenesis of congenital megacolon would be the study of the myenteric plexus (plexus of Auerbach) of the colon in cases of congenital megacolon in which postmortem examination had been performed. The myenteric plexus apparently has as its main function in the colon the conduction of stimuli and the coordination of movements and, as a result of such function, would be of importance in the pathogenesis of congenital megacolon. They studied the myenteric plexus in 11 cases of congenital megacolon, a series of cases used as controls and 5 cases of secondary megacolon. The myenteric plexus was found to be absent in the most distal part of the colon in all cases of congenital megacolon. In 80 per cent of the cases it was absent also in the "transitional region." In 60 per cent of the cases it was in addition absent in the lower part of the sigmoid. In 20 per cent of the cases the absence of the myenteric plexus extended from the rectum into the upper part of the sigmoid and the descending colon. In all cases of congenital megacolon there were nerves present in the location of the myenteric plexus which were not seen in the control cases. The authors conclude that the strategic location of the changes and a review of previous theoretic concepts, experimental studies and certain physiologic and anatomic studies point toward the significance of processes in the myenteric plexus in the pathogenesis of congenital megacolon.

**Classification of Epilepsies.**—Penfield stresses the great practical importance of proper classification. Patients with epileptic seizures may be grouped under cerebral seizures, focal cerebral seizures and idiopathic epilepsy. In the group of cerebral seizures, the pattern of attack may not be clear, but the exciting cause must be sought. In the second group, the initial pattern of attack is clear and the localization of discharge is evident, but it becomes necessary to discover the nature of the focal abnormality or the precipitating cause. Causes of cerebral seizures or of focal cerebral seizures include birth injury, cerebral abscess, trauma or tumor, congenital defect, disseminated sclerosis, hypoglycemia, infection, vascular disease, encephalopathy or toxemia. In the third group, the electroencephalogram is usually typical, being characterized by 3 per second, bilaterally synchronous waves. Most of these patients will be found to have "petit mal" lapses of consciousness; some will admit the occurrence of epilepsy elsewhere in the family, and all must be considered possible carriers of the tendency. When a patient is first seen, the pattern of the seizure may not be clear. Further study may reveal that his minor seizures consist in a tingling sensation in the left hand and that the *major* seizures begin with such a sensation. Thereupon, the patient is reclassified under the heading of focal cerebral seizures, somatosensory, cause unknown. Later, it may be obvious that he has an atrophic cerebral lesion, which seems to date from birth, and the diagnosis becomes "focal cerebral seizures, somatosensory; cause, birth injury." On the other hand, it may not be possible to work out the pattern of seizures, and yet the cause may be evident. In this event, the diagnosis would remain cerebral seizures, caused, for example, by cerebral vascular disease or by hypoglycemia. The author further discusses a classification based on age of onset. In every adult whose convulsive seizures begin after the age of 20 the epileptic state should be considered symptomatic of some other condition, such as trauma, neoplasm, arteriosclerosis, hypoglycemia or intoxication. Such a patient should be thoroughly studied. The author discusses roentgenographic, pneumoencephalographic and electroencephalographic studies and describes seizure patterns. When there is doubt as to the type of epileptic seizure or its localization, it may be wise to reproduce the patient's seizure by hyperpnea, continued for about ten minutes, or by requesting the patient to drink large amounts of water and administering pitressin® (beta-hypophamine) simultaneously. With regard to treatment the author says that for adults who have no obvious lesion of the brain, diphenylhydantoin and other recently recommended drugs may be best, but for patients who have an objective cerebral lesion, phenobarbital is more effective. The author recommends to all who are subject to seizures the following tetrad of personal precautions: (1) avoidance of alcohol, (2) avoidance of constipation, (3) avoidance of overfatigue from lack of sleep and (4) decrease of fluid intake to a minimum consistent with comfort. Attacks which can be controlled by medication and by observation of precautions should not be treated by surgical means, but when the focal nature of the attacks is established, and when the roentgenograms, pneumoencephalograms or electroencephalograms suggest the presence of a gross cortical lesion, then surgical treatment should be considered.

**Cerebral Vascular Lesions.**—This presentation by Cohn and his co-workers is the result of the compilation of data obtained from 130 patients showing disturbances of clinical and electrical function of the brain resulting from lesions of the cerebral vessels. Eighteen patients showed clinical evidence of subarachnoid hemorrhage. Eight patients had proved to have chronic subdural hematomas; 6 of these had preoperative recordings. The other 104 patients showed clinical signs of thrombosis, embolism or hemorrhage involving the cerebral vessels, with subsequent parenchymatous damage. Of these 104 patients, 12 died, and the brains of 11 of these patients were subjected to a detailed gross and microscopic examination. Each patient in this series was the recipient of one to several electroencephalographic examinations. All recordings were made with a Grass six channel electroencephalograph. Illustrative case histories and electroencephalographic tracings are presented. The authors arrive at the following conclusions: 1. Subarachnoid hemorrhage primarily induces minimal or moderate generalized abnormal electroencephalographic changes. Occasionally focal decreased electric output is also observed. 2. Subdural hemorrhage, in the main, acts as an intracranial space-consuming lesion. 3. Relatively superficial lesions (thromboses or hemorrhages) give rise to prominent focal slow wave activity. 4. Deep subcortical lesions give rise to little focal or general low frequency activity. 5. Patients with arterial hypertension show progressive electroencephalographic changes with continuing chronicity.

*Conical Cornea and Mongolism. A. Rados.—p. 454.

**Conical Cornea and Mongolism.**—Rados treated 2 patients, a man aged 22 and a woman aged 29, in whom bilateral conical cornea was associated with mongolism. The literature mentions as ocular symptoms of mongolism only nystagmus, convergent strabismus and blepharitis in some cases, in addition to the almost constant presence of the oblique palpebral fissure, with slanting of the lids up and temporalward and the epicanthus. Textbooks do not mention the concurrence of conical cornea with mongolism, but the author says that while the association of the two conditions was mentioned only occasionally in older reports, the accumulation of cases now indicates that the concurrence is not due alone to chance but belongs, like the cataract of old persons with mongolism, to the facultative characteristics of mongolian imbecility. The occurrence must, of necessity, be infrequent, since conical cornea is rare in young persons. It usually develops at about the age of puberty or shortly after; the majority of children with mongolism do not reach the age of puberty. The association of conical cornea with mongolism raises questions. In both conditions an endocrine disturbance, possibly polyglandular, may be operative, either primary or as a result of a general developmental abnormality in the germ plasm. The occurrence of conical cornea in cases of mongolism permits the conclusion that the nonhereditable form of keratoconus must be associated with endocrine imbalance characteristic of mongolism and that in the complex transmission of the anomaly the genetic factors may influence the cornea directly or through a possible inherited dysfunction of the endocrine glands.

**Studies on Stomach of Woman with Gastric Fistula.**—Crider and Walker point out that the circumstances which permit direct observation of the interior of the human stomach are rare, only 4 such cases having been described up to now. The possibility that physiologic activity in the stomach of the female may differ from that observed in the male is suggested by the strikingly greater incidence of duodenal and gastric ulcer (a 4 to 1 ratio) reported for males. The authors took advantage of the opportunity to study the interior of the stomach of a young woman who had undergone gastrostomy. Recordings were obtained of the motility of the antral region. The secretion of the stomach was allowed to flow out of the fistula by gravity and was collected in a glass beaker. The gastric juice was analyzed for combined and free hydrochloric acid, pepsin and bile; the general character of the secretion was noted, and subjective sensations such as hunger pangs and heartburn were recorded. The color of the mucosa was observed. A cyclic motility was observed. The interval between cycles and the magnitude of contractions varied considerably. Two types of contraction were seen, i.e., a basic kneading type and a peristaltic type. A cyclic type of motility at the cardiac sphincter was noted. Under standard conditions, with the patient fasting and in a happy and cooperative mood, a moderately active, secreting stomach with a relatively red mucosa was observed.

Anger, resentment, fear and anxiety were associated with decreased motility and secretion of the stomach and with blanching of the mucosa. It was also noted that the secretion had a lower hydrochloric acid content. Heartburn, nausea, retching and a reflex of bile-stained secretion were caused by mechanical stimulation in the region of the cardiac sphincter. Menstruation did not have any appreciable effect on the behavior of the stomach. Periods of sleep appeared to have little effect. Painful stimuli caused a pronounced increase in the motility of the stomach but had little effect on the secretion or on the color gradient. The absence of hypersecretion and hypermotility under conditions of sustained emotional tension in this patient was in striking contrast to their presence in male patients previously studied.

**Stricture of Bile Ducts: External Hepaticostomy Followed by Spontaneous Hepatoduodenal Fistula.**—Walters and Marvin of the Mayo Clinic report 6 cases of complete stricture of the extrahepatic bile ducts in which external hepaticostomy was followed by the spontaneous development of a hepatoduodenal fistula. In 5 of these cases no effort was made to create an anatomic condition which would favor the development of such a fistula. A rubber catheter was sutured into the intrahepatic duct to create an external biliary fistula in the first 2 cases. It was the intention of the surgeon to transplant the fistulous tract into the intestine at a later date, but a fistula developed between the bile duct and the intestine in the interim. Owing to the gratifying result obtained in these cases, Walters decided to use a similar surgical procedure in the next case of complete stricture of the extrahepatic bile ducts in which an anastomosis could not be effected between a patent bile duct and the intestine. A slight modification of the technic was employed in case 6. In this case the duodenum was brought up and sutured to the under side of the liver. The sutures were tied tightly. It was hoped that this would produce necrosis which would favor the development of a hepatoduodenal fistula. It was expected that this modification might assist in the development of a fistula into the duodenum, which it did. Unfortunately the fistula closed after the removal of a catheter from the sinus tract. In 5 of the 6 cases the patients have had few, if any, symptoms of biliary obstruction for periods ranging from six months to eight years after the operation.

**Pancreatitis Causing Obstruction of Bile Duct.**—After commenting on the rarity of chronic pancreatitis and on the difficulty of differentiating it from carcinoma of the pancreas, the Behrends review the literature on the condition and discuss etiologic factors, the symptomatology, the diagnosis and treatment, and present histories of 10 cases. Only 1 of the 10 patients reported had stones in the gallbladder. This is characteristic, stones in the biliary tract being exceptional in the presence of chronic pancreatitis. All except 2 of the patients had jaundice. The first patient treated by the authors was subjected to choledochostomy, with T tube drainage. Five underwent cholecystoduodenostomy. In 1 case a choledochoduodenostomy was performed, and in another cholecystojejunostomy was followed by choledochogastrostomy. In all cases the pancreas was hard, and it was most difficult to differentiate between chronic pancreatitis and carcinoma. If patients operated on live over five years, this fact can be taken as reasonable evidence that cancer of the pancreas or of the papilla of Vater was not present. All but 1 of these patients lived for five years or more in good health. The authors stress the following points: 1. Chronic pancreatitis may cause complete or incomplete obstruction of the common bile duct. 2. The cause is still undetermined. 3. There may be some connection between congenital fibrocystic disease of the pancreas and chronic pancreatitis. 4. The symptoms are not always suggestive of pancreatic disease, but may simulate those of cholelithiasis or those of carcinoma of the head of the pancreas. 5. Jaundice may or may not be present in chronic pancreatitis. 6. The diagnosis of chronic pancreatitis is difficult to establish, even after the abdomen has been opened. 7. It is necessary to differentiate between chronic pancreatitis and carcinoma of the head of the pancreas. 8. When there is doubt, a biopsy should always be made; an internal anastomosis is preferred to the use of the T tube after a choledochostomy.

**Growth of Bacteria on Cellophane.**—Reed and McKercher describe a method for the cultivation of bacteria on the surface of sheets of cellophane spread over layers of absorbent material such as cotton saturated with any fluid medium. The method has proved to be useful in preparing suspensions of bacteria reasonably free from contamination by the culture medium.

**Assessment of Hospital Diets.**—Hunter and his associates undertook an investigation to ascertain the nutritional adequacy of twelve hospital diets. All diets were collected at the Edmonton Hospital by a trained dietitian and assayed in the laboratory for vitamin A and carotene, thiamine, riboflavin, nicotinic acid, ascorbic acid, calcium, phosphorus, iron and protein. The diets were found to be deficient in various respects, and particularly in the B vitamins, ascorbic acid and iron. There is no scientific evidence to support the belief that large amounts of vitamins hasten healing and regenerative processes except where there has been previous deficiency. The average convalescent patient therefore needs no more than the ordinary sedentary person. The authors feel that, as proper nutrition is a fundamental basis of health and patients are in a hospital to regain health, the general adequacy of a hospital diet should not be open to question. Where there is faulty nutrition in the local population, the hospital meals should be designed to counteract such conditions rather than perpetuate and even exacerbate them.

**Clinical and Laboratory Aspects of Chronic Recurrent Pancreatitis.**—Muether and Knight report 58 patients, 28 men and 30 women between the ages of 20 and 80, with chronic recurrent pancreatitis. The symptoms and physical findings during remissions were at best suggestive and never diagnostic. The persistence of abdominal pain, food intolerance and diarrhea, particularly when associated with exacerbations which subside on symptomatic treatment and when not associated with demonstrable disease in the gastrointestinal tract, liver or gallbladder, should suggest the presence of chronic pancreatitis. The serum diastase levels are diagnostically elevated during exacerbations and may remain elevated during remissions. Any reading above 200 units is definitely abnormal. Extremely low serum diastase level below 80 units may be seen in far advanced pancreatic disease. The glucose tolerance test, serum cholesterol and stool examination are of little aid in the diagnosis of chronic recurrent pancreatitis.

**Serum Diastase Levels in Chronic Recurrent Pancreatitis.**—Knight and his co-workers investigated the response of the serum diastase levels of 44 patients with chronic pancreatitis, of 22 patients with miscellaneous diseases in which it was believed that the pancreas was not involved and of 10 normal control persons to neostigmine methylsulfate. The serum diastase values were remarkably constant in normal controls and in patients without pancreatic disease after stimulation of the pancreas with neostigmine methylsulfate. When the pancreas was stimulated in patients with chronic pancreatitis, abnormal serial diastase values were obtained, depending on the degree and type of damage as follows: In group 1, consisting of 21 cases, the fasting diastase values were normal or elevated; after stimulation with neostigmine there was a progressive fall in the serial diastase values. This type of curve is indicative of pancreatic cellular disease without ductal or intrapancreatic obstruction. In group 2, consisting of 15 cases, the high or normal fasting diastase value showed a slight rise after stimulation followed by a progressive fall to values equal to or lower than the fasting level. This type of response indicates pancreatic cellular disease with an associated mild ductal obstruction. In group 3, consisting of 6 cases, the fasting values were normal or elevated. Stimulation with neostigmine was followed by a progressive rise of the serial serum diastase values. This response indicates pancreatic cellular inflammation with persistent intrapancreatic obstruction. The fourth type of response was seen in 2 patients in which the process was so far advanced that the gland no longer responded to stimulation, yielding a low flat curve. Seven cases of carcinoma of the pancreas were studied. In 5 of them a high fasting diastase value was obtained which was followed by a progressive increase in the serial diastase level. This type of response is seen in patients in whom there are present pancreatic cells capable of secreting enzyme with complete obstruction to the flow of these pancreatic enzymes into the gastrointestinal tract. In the 2 remaining cases there were abnormally low fasting diastase values; on stimulation of the pancreas no change in the serial diastase values was observed, probably representing complete atrophy of the gland as a result of prolonged obstruction.

**Gamma Globulin in Epidemic Infectious Hepatitis.**—Volwiler and Dealy treated 2 Army officers, aged 29 and 23, who had chronic epidemic infectious hepatitis, with 200 cc. of normal human serum gamma globulin administered intramuscularly over a period of one month; 20 cc. was injected on alternate days for five doses; thereafter, 20 cc. was given twice weekly for another five doses. This schedule was planned so that a high titer of circulating antibody would be rapidly attained and subsequently maintained over a period of several weeks. This therapy did not alter the clinical pattern of the 2 patients. If the chronic phase of hepatitis is perpetuated by the periodic release of active virus from the disintegrating necrotic parenchymal cells, the therapeutic ineffectiveness of even long-maintained passive immunity of this kind is not surprising when one considers the histologic features of this phase of epidemic hepatitis. In spite of the characteristic persistence of periportal and focal intralobular inflammation, actual necrosis of parenchymal cells is infrequent, and when present probably proceeds at a very slow rate. If live virus is contained within parenchymal cells, it is probably beyond the reach of the circulating antibody.

**The Nervous Patient and the General Practitioner.**—Alvarez shows that although the family physician is frequently helped in making a diagnosis by knowing the patient and his background, the average physician does not think often enough of a neurosis. Physicians sometimes fail to recognize a neurosis among their own relatives. The author deplores that professors in medical schools are much too inclined to neglect the neuroses and to demonstrate in the amphitheater examples of only the most rare and bizarre organic diseases. The teacher should remember that his students will rarely, if ever, see or recognize one of these diseases. What they will see every day will be nervous men and women with negative reactions to tests and all sorts of distress everywhere: backaches, headaches, dysmenorrhea, flatulence, fatigue and lack of energy. One of the bad features of medical practice today is that physicians so often try to diagnose neurosis only by exclusion. A patient is put through all the tests, and if negative reports are obtained, a neurosis is diagnosed. The disadvantage of this procedure is that in tests slight abnormalities may be disclosed which have nothing to do with the illness, but which satisfy the examiner and lead him to conclude that the diagnosis is made; the real disturbance, however, goes on unrecognized and unrelieved. The author warns against trying to make a diagnosis from one test and against placebos of diagnosis such as low blood sugar, low blood calcium, floating kidney and the like. The way the history is told frequently differentiates the patient with organic lesions from the nervous patients in whom the disorder is functional. The author cites syndromes that are always functional in nature, giving particular attention to migrainous disorders, and to gastrointestinal distress not related to meals or defecation.

**Hemophilia-like Disease in Women.**—According to Hewlett and Haden, it has never been conclusively determined whether hemophilia can occur in women, although a few cases which clinically resemble hemophilia have been reported in women. The authors present the histories of 2 such women whom they observed in recent years. The clinical picture in these 2 cases was similar to that found in true hemophilia, and the outstanding characteristic was the prolonged coagulation time of the blood. The coagulation time of recalcified plasma, which Quick believes pathognomonic for hemophilia, was positive in both patients. When normal citrated plasma was added to blood from one of the patients the coagulation was greatly accelerated. This is similar to the response of hemophilic blood to normal plasma. Tiselius protein fractionation revealed definite abnormality in the alpha-globulins in one patient and suggestive but not conclusive evidence of such abnormality in the second patient. The authors believe that these changes are significant. The possibility that some acquired change in the plasma protein pattern might be the basis for the coagulation defect in these patients is suggested. The defect seems similar to that found in hemophilia.

**Mumps Vaccine in Volunteers.**—Muntz and his associates present data on the intracutaneous use of nonviable mumps vaccine on human volunteers, including medical students, nurses and patients at the Indiana University Medical Center. Two strains of virus were used, but no difference was found between the two strains. The strains were propagated on chick embryos. Vaccine was prepared from the heat-killed virus. Two complement-fixing units (0.1 cc. of vaccine) were injected intradermally. Hypersensitive reactions seemed to indicate previous contact with the virus in the subclinical or clinical forms. In addition, the same hypersensitivity developed after the first intradermal dose. The mumps vaccine given the volunteers served as an index of potential susceptibility to mumps, and a positive reaction implied a previous clinical or subclinical infection with the virus. The skin test dose caused significant rises in complement-fixing antibody titers and might possibly be a practical method of vaccination. Work is in progress to determine the optimal dose and route of administration. The vaccine caused no untoward reaction on 400 human subjects. There is as yet no evidence that the immunity which the intradermal vaccine produces will be permanent. Follow-up studies of the volunteers will be necessary. The potential value of the mumps vaccine has, in part, been determined. The actual value of mumps vaccine remains as an unsolved problem. Long term immunologic-epidemiologic studies will be necessary.

**Debridement: Obsolescent or Essential.**—Pomerantz gives a description of debridement as it was practiced in an evacuation hospital during the recent war. He stresses that debridement properly done prevents wound sepsis, anemia and general morbidity. The advent of biotherapeutic agents does not make debridement unnecessary. Clostridial cellulitis is amenable to large doses of penicillin, but the more advanced myositis is not. Cases are described in which local injection was of value in the treatment of clinical clostridial cellulitis. The author also describes debridement in the presence of jaundice and following phosphorus burns.

**Psychosis Following "Amateur Hypnosis."**—Dribben presents the case of a youth, aged 17, who had been recently inducted and who was brought to the hospital in a state of acute excitement, with complete detachment, incoherence, confusion and disorientation. A group of enlisted men had been attempting mesmeric hypnosis for amusement, and one of them had succeeded in hypnotizing the patient but had been unable to "bring him back." After a short period in the receiving office, the patient became less excited, and contact was restored, but he remained amnesic in respect to his own identity and to the incidents immediately prior to his hypnosis. The following morning there was a recurrence of the amnesia and confusion. He was then taken by his "buddies" to another hypnotist, who attempted mesmerism with constructive suggestions. This produced a temporary improvement. The same night, when he was brought back to the hospital, he was lethargic, detached, disoriented, confused and amnesic, particularly in regard to the hypnosis episode. Auditory hallucinations were noted. The lethargy and a mild detachment persisted. He developed an insight into the psychotic episode, and believed that it was caused by the hypnosis. Later he was separated from military service. This youth, who was constitutionally handicapped and had a schizoid diasthesis, reacted with psychosis to hypnosis by unqualified "amateur" mesmerists.

**Right and Left Handedness.**—Eustis points out that the physician who is asked whether it is safe and wise to train an apparently left-handed child to use pencil and pen with his right hand can find good authority in the literature for almost any answer he may choose to give. Eustis believes that many apparently left-handed primary grade children may be successfully taught to write with the right hand. When writing begins they should all be so taught, because the use of the right hand fits in better with the left to right direction of writing and also because it conforms to the custom of the majority and hence is easier psychologically. If, however, a child objects strenuously or shows signs of nervous strain, of which stuttering may be one, the attempt should be abandoned at once, and he should be allowed to use his left hand without criticism. Those who are taught to write with the left hand should be shown the proper position of the paper, which is slanted with the top border to the right instead of to the left as is usual. It is often necessary to drill them in the use of this position, since otherwise they are likely to imitate their right-handed neighbors. They should also be allowed to write with a slight backhand slant if they so prefer.

**Berylliosis.**—Machle and his associates define berylliosis as a general disease characterized clinically by pulmonary insufficiency and with the major pathologic changes in the lung. It results from the inhalation of finely divided beryllium compounds. The characteristic lesion is a granuloma, like that seen in sarcoidosis. The major clinical syndromes associated with exposure to beryllium are: conjunctival irritation, irritation of the upper respiratory tract, dermatitis, subcutaneous granulomas, acute berylliosis and chronic berylliosis. There is a wide range in the pattern—from a case in which the patient dies with symptoms of a violent acute pneumonitis two weeks after onset, to a case in which the patient has roentgenographic evidence of disease six years after termination of exposure but is without clinical disability. An attack of acute disease has been followed two years later by the onset of chronic berylliosis, and gradations of intermediate degree occur. The differentiation between acute and chronic pulmonary disease is purely arbitrary. Diagnosis on the basis of the physical findings is not possible. The symptoms and signs, however, taken together with the characteristic onset and course, plus a history of exposure, may lead to presumptive diagnosis. Sarcoidosis, erythema multiforme, periarteritis nodosa, chronic pneumonia, miliary tuberculosis, mediastinal lymphoma, lymphangitic spread of carcinoma, mitral stenosis, Hodgkin's disease, moniliasis, other fungous disease of the lungs and the pneumonoconioses may all simulate berylliosis. The fatality rate has been estimated at 20 per cent. In situations where sizable groups of cases occurred, fatality rates ranged from 10 to 26 per cent. The prognosis in the individual case must be based on the type of onset, course and severity. The best treatment is supportive. The pulmonary insufficiency often requires use of oxygen. In the cases of mild disease, general supportive treatment with exercise to limit of comfort is indicated; in the cases of severer disease, rest in bed and continued oxygen therapy are necessary. In several cases, penicillin-streptomycin aerosol therapy was of value in dealing with intercurrent infections, but did not alter the course of the underlying disease. Specific treatment designed to aid in the elimination of beryllium, such as BAL and solubilizing agents, was without effect. Prophylaxis is now a major concern of industries handling beryllium.

**Pulmonary Disease in Beryllium Workers.**—Vorwald says that the pathologic aspects of the disease seen in beryllium workers are confined principally to the lungs and tracheobronchial lymph nodes. Two distinct types of change are recognized: (1) the acute form, which resembles a pneumonic process, attended by edema, hemorrhage and exudate, but without the polymorphonuclear leukocytic response that accompanies an acute infectious process, and (2) the chronic form, which is characterized by the presence of a diffuse pulmonary reaction and scattered granulomatous lesions throughout both lungs.

**Isolation of Brucella from Apparently Healthy Persons.** —McVay and his associates point out that in recent years the isolation of Brucella organisms from cases of Hodgkin's disease has caused considerable discussion. The confirmation of this finding in their laboratory and the statements in the literature that these organisms could be isolated from patients with various infections led the authors to seek an explanation. Since Brucella organisms are known to multiply in macrophages and fibroblasts, it was thought that cultures of enlarged prostates and fibrosed fallopian tubes might reveal the presence of these organisms. At present 34 prostates have been cultured. From these cultures Brucella abortus has been isolated in 2 instances and Brucella melitensis in a third. Forty-three fallopian tubes have been similarly studied. From one of these Br. melitensis has been isolated. Although none of the patients from whom Brucella organisms were obtained had any unusual symptoms prior to operation, a review of their histories revealed in all 4 cases a history of country life and contact with cows and other farm animals. In 1 instance the patient had been in contact with an animal infected with brucellosis. In all cases there was a history of the consumption of raw milk. All of the patients had a clinical record of illnesses compatible with brucellosis. None of these illnesses, however, had occurred in recent months. The serum of all 4 patients lacked agglutinins for Brucella, while their skin gave strongly positive reactions with Brucella antigen. The authors believe that brucellosis is endemic, at least in certain parts of the world, and that the organisms may be carried by a number of apparently healthy persons.

**Orchiectomy in Cancer of Bladder.**—Hebert performed orchiectomy in 4 men aged 81, 49, 60 and 55 with cancer of the bladder. The patients presented hematuria, pollakiuria, vesical tenesmus and severe pain before the intervention. In the case of the patient aged 81 high voltage irradiation therapy had been practiced in vain for two weeks before the orchiectomy. The hematuria subsided within forty-eight hours after the orchiectomy, and the patient urinated every hour instead of every five minutes, as before the operation. He had no pain and less tenesmus. The patient died six months later from bronchopneumonia, but he was free of urinary symptoms during these last months of his life. The patient aged 49 was given 5 mg. of diethylstilbestrol daily after the orchiectomy. He made a complete recovery and is perfectly normal two and a half years after the operation. The third patient, aged 60, was given high voltage irradiation therapy after the orchiectomy. One and a half years after the operation he has no urinary symptoms and the appearance of the bladder is normal with a capacity reduced to 150 cc. The fourth patient, aged 55, was operated on in June 1948, and it is still too early to draw any conclusions. Cancer of the bladder situated at the bottom and near the neck of the bladder shows a better response to orchiectomy combined with hormone therapy than cancer involving the periureteral region. Fulguration, excision of the tumor and deep irradiation therapy should be combined with orchiectomy and hormone therapy.

**Tuberculosis at the Crossroads.**—Stallybrass says that mortality from tuberculosis has always been regarded as one of the best indexes of the sanitary well-being of a community. In 1847 the English mortality from phthisis was 3,189 per million; nearly a century later the standardized death rate was 528 per million, one-sixth of what it was in 1847. There is evidence that the great decline in tuberculosis mortality that occurred in the later two thirds of the nineteenth century was caused mainly by improvement in socioeconomic factors, of which the rise in the real value of wages is the best gage. This rise in value resulted from the increasing productivity of machines; it facilitated better nutrition and housing, and in the home it involved a lessened exposure of women, and more especially children, to infection. In recent decades sanatorium accommodations providing segregation for early cases has become increasingly effective in preventing the spread of tuberculosis. However, family contacts and the infection of nurses still present serious problems in combating tuberculosis. The author suggests that vaccination with BCG or the vole Bacillus might meet the needs as a preventive for these two groups.

**Congenital Tuberculosis.**—The case presented by Jordan and Spencer was that of a mother and her infant. During routine antenatal examination in October 1947 it was discovered that the woman had pulmonary tuberculosis. She was delivered in May 1948. The infant, a boy, was apparently healthy at birth, and was immediately separated from the mother, but at his twenty-second day he began to take his feedings poorly, was lethargic and had fever. The abdomen became distended and jaundice appeared. The infant died thirty days after birth. Postmortem examination disclosed disseminated tuberculosis and caseous tuberculosis in the lymph nodes of the hilus of the liver. The postmortem examination of the mother, who died about three weeks after her delivery, revealed generally disseminated tuberculosis, tuberculous peritonitis and salpingitis and chronic pulmonary tuberculosis. The authors consider this case as one of congenital tuberculosis, because postmortem examination showed tuberculous lesions commensurate in size and distribution with intrauterine infection. Whether these were due to blood-borne infection through the umbilical vein or to ingestion of infected amniotic fluid is uncertain, but infection was more likely to have been through the former route, as the glands in the porta hepatis were those most enlarged. Postmortem examination of the mother revealed active genital tuberculous lesions, which were certainly present during the latter part of the intrauterine life of the child. Immediate removal of the child from contact with the mother and failure to find tuberculous infection among members of the staff attending the child make it almost certain that the mother was the source of infection.

**Anticonvulsive Action of Paraldehyde.**—De Elío and his associates recently tried paraldehyde by intravenous injection in the treatment of convulsive states produced in the course of neurosurgical operations. The good results obtained have been the basis for an experimental and clinical study of this drug. The authors stress that the toxicity of paraldehyde is low. It can be injected intravenously in doses of up to 0.2 cc. per kilogram without ill effects. Large doses have a narcotic action. The motor responses of the cerebral cortex of the cat and human beings are greatly reduced or abolished by small doses of paraldehyde. Convulsive attacks produced in the course of neurosurgical operations by cortical stimulations are immediately stopped by paraldehyde. Paraldehyde reduces or abolishes for some minutes the spontaneous cortical activity of the cat. Convulsive discharges of the cortex elicited by pentamethylenetetrazol (metrazol®) disappear immediately with the injection of paraldehyde. The anticonvulsive action is also very striking in animals given injections of convulsant drugs. A dose of paraldehyde protects an animal against large doses of strychnine and metrazol.® The anticonvulsive action appears also in the decerebrate and spinal preparations. Clinically, paraldehyde has been used in many cases to stop operative or postoperative convulsions. The authors maintain that paraldehyde injected intravenously in doses of 0.05 to 0.1 cc. per kilogram is the best agent available to break up and stop a convulsive discharge. The dose may be repeated if necessary.

**Intestinal Lipodystrophy.**—Intestinal lipodystrophy was first described by Whipple in 1907; since then only about 25 cases have been reported. Most patients have been middle-aged men, and the duration of symptoms before death has usually been one to five years, though sometimes much longer. Stabbing central abdominal or epigastric pain has been common at the outset. Fever is not always present, and bleeding per rectum, when sought for, has been more often found than not. A history of "arthritis" affecting more than one joint has been given by some patients. Increasing lassitude, loss of weight, diarrhea and steatorrhea herald the terminal phase. Brown pigmentation of skin and oral mucosa and hypotension have often suggested Addison's disease. Anemia, achlorhydria, signs of vitamin deficiencies, hypoproteinemia, ascites and edema may appear before the end. The case presented here concerned a man aged 44. It does not differ materially from those previously reported. Abdominal pain was the presenting symptom and did not persist. Pigmentation together with hypotension suggested Addison's disease, but biochemical investigations, the normal reaction to the Robinson-Power-Kepler test and a lack of response to specific therapy contraindicated adrenal insufficiency. Whipple's disease may possibly originate in a primary nonspecific "jejunitis." The patient's personality coincided broadly with that found in regional ileitis and some other intestinal disorders believed to be psychosomatic.

**Plasma Protein Level and Disappearance of Evans Blue from Blood Stream.**—Rossiter found that there was a negative correlation between the slope of the disappearance curve of Evans blue, injected into the blood stream of patients with different degrees of hypoproteinemia, and the plasma protein level. The correlation was entirely with the level of albumin and not with that of globulin. The author stresses that in the determination of plasma volume by the dye method disappearance curves should always be plotted. The plasma volume should never be calculated from a single estimation of the plasma dye level, especially when the plasma protein level or the albumin-globulin ratio is abnormal.

**Benadryl® in Parkinsonism.**—Ryan and Wood say that in 1947 a patient with advanced parkinsonism, who was bedridden owing to extreme rigidity and had not responded satisfactorily to classic treatment, was given diphenhydramine hydrochloride (benadryl® hydrochloride). The result was so dramatic that search was made for similar cases. The series now includes 40 cases. The 2 case histories presented indicate that the diphenhydramine was administered in 50 mg. doses three or four times a day. Reviewing their observations on 40 cases, the authors say that within ten days the therapeutic effect reaches its maximum. Thereafter increase in dosage cannot be expected to produce any further improvement. Physical therapy and rehabilitation exercises are useful when the greatest relaxation has been attained. Diphenhydramine can be used in conjunction with the classic forms of treatment. When it is intended to treat with diphenhydramine a patient already receiving belladonna, it is unwise to stop the latter suddenly. In postencephalitic parkinsonism sudden withdrawal of the patient's usual medicine may lead to a severe oculogyric crisis, which will prejudice him against the new treatment. Diphenhydramine does not cure; its effect is purely palliative, and complete relapse occurs within forty-eight hours of withdrawal. No case in this series showed any toxic effect. Two of the patients have now taken 200 mg. daily for over eighteen months without ill effects.

**Radical Surgery in Squamous Carcinoma.**—Raven calls attention to the value of radical surgical excision in certain types of advanced squamous carcinoma. The 5 patients whose case records are cited were unsuitable for any other form of treatment than surgery. They included 1 case each of: carcinoma of the tongue; of the maxilla, nose and face; of the alveolus and mandible; of the ear and petrous bone, and of the penis. The patients with carcinoma of the tongue and of the penis were pronounced hopeless; after radical operation the 2 patients have lived busy and useful lives for seven years without recurrence. The patient operated on for carcinoma of the ear and petrous bone was also returned to work and was free from recurrence eleven months after operation; twenty-two months after operation there is local recurrence, but his general health is good. The authors describe the treatment of lymph nodes, postoperative irradiation and the repair of defects. They emphasize the importance of team work in the management of these advanced cases of carcinoma.

**Anti-Lewis Serum in Australia.**—Krieger and Simmons point out that in 1946 Mourant of Britain reported a "new" human blood group antigen which occurred in 25 per cent of the English population. The "new" agglutinogen, which was called the Lewis antigen, was shown to be independent serologically of the ABO, MN, Rh, P and Lutheran systems. Limited family studies showed that the agglutinogen is inherited and is probably a dominant mendelian character. After briefly mentioning the first Australian report on the Lewis antibody, presented by Jakobowicz and her co-worker in 1947, the authors present what they believe to be the second Australian case report on the Lewis antibody. Their patient was a single woman, aged 45, who, because of low concentration of hemoglobin, was given 2 pints of apparently compatible group O blood on the same day. No reaction was observed. Four weeks later a second transfusion of group O blood was commenced. A severe reaction developed with vomiting, severe rigor and anuria after 200 cc. of this blood had been given. The author describes tests made on the serum of this patient and on the serum of the first Australian patient with the anti-Lewis serum and also on four anti-Lewis serums provided by Mourant. Almost identical reactions with a large number of group O cells were obtained with all six antiserums. The reactions in all cases were stronger at room temperature (20 C.) than at 37 C. The two donors whose blood was given in the first transfusion to the patients whose case is reported here have since been tested and the blood of one was found to contain the Lewis antigen while that of the other did not. Although it was not possible to test the blood of the donor used in the second transfusion for the Lewis factor, it can reasonably be assumed that he had the Lewis antigen in his blood and that the transfusion of his blood caused the reaction in the patient who had become immunized to this factor as the result of the first transfusion. Subsequent tests on samples of the patient's serum during a period of eight months following the transfusion reaction revealed a progressive deterioration in the titer of the Lewis antibody to scarcely detectable levels.

Reduction in Coronary Flow by Pituitary (Posterior Lobe) Extract in Relation to Action of Nicotine and to Smoking. Edith Blübring, J. H. Burn and J. M. Walker.—p. 73.

**Effect of Smoking on Diuresis.**—According to Walker it is generally known that nicotine stimulates the sympathetic ganglions. Various observers have shown that the amount absorbed from one or two cigarets is sufficient to raise the blood pressure by 20 mm. and the heart rate by 10 to 12 beats per minute. Recently the liberation of the antidiuretic hormone has been described. This paper presents further studies on the antidiuretic effect of smoking. Experiments on 13 students showed that inhibition of water diuresis was caused by the smoking of one cigaret in 7 subjects and of two cigarets in 6 subjects. Nonsmokers were more susceptible to the effect of smoking than smokers. In 3 students the intravenous injection of 1.6 to 3.0 mg. of nicotine acid tartrate inhibited water diuresis. The inhibitory effect of smoking and nicotine was accompanied by a rise in the total chloride excretion and was probably due to the liberation of posterior pituitary hormone. The effect of smoking was of the same order as that of the intravenous injection of 50 milliunits of pituitary (posterior lobe) extract. There is evidence that the inhibition of water diuresis was not due to a nonspecific effect of the nausea that often accompanied smoking or the injection of nicotine. Morphine in therapeutic doses does not inhibit water diuresis in man.

Treatment of Fibroadenomatosis Mammae with Short Wave Therapy. H. Mossberg.—p. 415.

**Radiation Injuries Produced by Contact Roentgen Therapy.**—Poppe defines contact roentgen therapy as the treatment with a short target skin distance, low voltage and great intensity. The technic used at the University Hospital of Oslo employed a target skin distance of 18 mm. unfiltered, or 22 mm. with additional filter, 2 milliamperes and 50 kilovolts. Contact roentgen therapy was used particularly for skin cancer. The dosage was 4,000 to 5,000 r applied in a single treatment. In some cases a disfiguring scar with telangiectasis remained after treatment. In 17 of 1,384 cases in which the dorsal surface of fingers or toes had been treated with roentgen contact therapy, swelling and tenderness persisted for several months after treatment and occasionally ulcerations developed. In addition to these 17 cases, the author cites 7 cases in which definite injuries resulted after contact roentgen ray therapy. In 2 of these the lesions were in the region of the ear, and in the other 5 they developed on the dorsal surface of toes and fingers after treatment of warts and keloids. The author stresses that the use of contact roentgen therapy on hands and feet demands special precautions. If it appears impossible to give the treatment without using an additional filter, it is preferable to adopt other methods—e.g., electrodesiccation. It would be an advantage to have an apparatus which could be operated at a lower voltage, down to 20 kilovolts, so that an even greater fall of intensity with depth could be obtained. If the apparatus with a tension of 50 kilovolts is used, it is safer to fractionate the dose when the treatment is applied to fingers and toes.

"Saving Adjustment" of Blood Metabolism to Albumin Deficiency. H. Overkamp.—p. 172.
Preliminary Report on Observations in Prisoners of War Returning Home with Tendency to Edema with Regard to Rheumatism and Foci. H. Wortmann.—p. 174.

**Independence of Heart Dynamics and Electrocardiogram.**—According to Blumberger, cardiac force, function and decompensation depend on mechanical or dynamic processes, which may be measured by the changes in pressure, volume and time. They may be modified by peripheral influences to a greater extent than the electrocardiogram. The mechanical and the so-called electric duration of the systole are not always the same, and both may undergo changes in opposite directions. In hypertensive persons an increase in the maximum systolic blood pressure from 160 to 220 mm. of mercury and of the medium blood pressure from 120 to 146 mm. of mercury causes considerable prolongation of the first period of the ventricular systole and shortens the expulsion period. This indicates clearly a slowing of the rise of the systolic pressure in the ventricles and a reduction of the cardiac output. The electrocardiogram, however, is not influenced. The same differences may be demonstrated with an alternating pulse. Longer first periods of the ventricular systole and shorter periods of expulsion are associated with a smaller rather than with a stronger pulse, while alternations of the cardiac function are as a rule without influence on the electrocardiogram. The electrocardiogram of patients in whom damage to the cardiac muscle of myocardial nature has been diagnosed early during the two last years of the war showed characteristic changes, while studies of the first period of the systole and of the period of expulsion suggested a normal heart action. Changes in the duration of the isometric and isotonic contractions occurred only in patients with simultaneous decompensation of the heart. Purely muscular insufficiency of the heart was observed many times without the slightest change in the electrocardiogram. Complete dynamic compensation of the heart may be obtained by treatment, without a corresponding change in the electrocardiogram. One should avoid the common error of evaluating the heart function on the basis of the so-called exertion—or work—electrocardiogram.

Combat of Postoperative Thrombosis and Embolism. T. Heynemann.—p. 8.
Value of Postoperative Irradiation in Uterine Carcinoma. H. Kirchhoff.—p. 17.
*Irradiation of Spleen. R. K. Kepp.—p. 24.
Clinical Aspects of Adenocarcinoma of Uterine Cervix. H. Drescher.—p. 31.
Heat Coagulation of Cervical Mucosa in Chronic, Refractory Cervicitis. O. H. Moell.—p. 57.

**Irradiation of Spleen.**—According to Kepp irradiation of the spleen was introduced into gynecologic therapy after attention had been called to its favorable effect on blood coagulation. Irradiation is carried out with 180 or 200 kilovolts and a 0.5 mm. copper filter. The focus distance is 40 cm. and the size of the field 6 by 8 or 8 by 10 cm. After the location of the spleen has been determined by percussion, the roentgen tube is directed slightly upward so that irradiation of the ovaries is avoided. The rays as applied by the author produce a surface dose of about 135 r, of which about 60 r reach the spleen. This dosage produces no undesirable secondary effects.

The author reviews results he obtained in 65 cases. So-called juvenile hemorrhages accounted for the majority (39) of the cases. Functional hemorrhages in sexually mature women and in women of the menopausal age, hemorrhages in the presence of adnexitis and hemorrhages resulting from thrombopenia were the other conditions for which irradiation of the spleen was done. In nearly three fourths of all the patients the existing hemorrhage was arrested by the irradiation. Regulation of the menstrual cycle was effected in 40 per cent of the cases. The mode of action of this treatment has not been explained, but it is assumed that the coagulability of the blood is increased by the products of destruction deriving from the splenic parenchyma, which is highly sensitive to irradiation.

*Sacroiliac Joint: Changes During Pregnancy and Injuries During Delivery. *I. Györffy.—p. 23.*
Question of "Clear Cells" in Mucosa of Human Uterus. F. Feyrter and J. Froewis.—p. 33.
*Early Recognition of Air Embolism During Operation for Myoma. W. A. Jauch.—p 49.

**Sacroiliac Joint: Changes During Pregnancy and Obstetric Injuries.**—Györffy points out that the joints of the pelvic region become more mobile during pregnancy. The sacroiliac joints supposedly undergo changes similar to those occurring in the symphysis. The sacroiliac joints may become damaged during delivery and even during pregnancy. Injuries to the ligaments and capsules and the resulting hemorrhages may bring on pains that may be so severe that the patient is obliged to remain immobilized for weeks until healing takes place. The author recommends application of a plaster of paris cast in order to insure complete rest for the pelvic region.

**Early Recognition of Air Embolism.**—Jauch reports the case of a woman, aged 48, who was operated on for a large myoma of the uterus. Immediately on the exposure of the myoma a large vein could be seen, which emerged from the tumor to the surface. By pulling on the large tumor (the size of a man's head) negative pressure was produced in the abdominal cavity, which became audibly equalized after the largest part of the tumor had emerged from the abdominal incision. Immediately a chain of pea-sized to bean-sized air bubbles could be seen in the vein passing along the surface of the tumor and streaming in the direction of the uterine cervix. Manual pressure was exerted at once in order to prevent further passage of air bubbles from the tumor circulation to the patient's body circulation. Pressure was maintained until the uterine vessels had been clamped and divided. The author believes that only a small quantity of air entered the patient's general circulation. It is generally assumed that a small amount of air is tolerated without symptoms.

*Extragenital (?) Chorionepithelioma Appearing as a Primary Solitary Tumor of the Lung in a Man. L. D. Eerland.—p. 5.
Amebic Dysentery and Amebiasis. P. B. van Steenis.—p. 11.
*Hypercalcemia in Besnier-Boeck's Disease. S. A. Westra and J. F. Visser.—p. 18.

**Extragenital Chorionepithelioma Appearing As a Solitary Lung Tumor.**—Eerland presents the case of a man, aged 25, who complained of pain in the side and coughing. Roentgenoscopy of the thorax disclosed a round shadow, and pulmonary echinococcus was thought of but could not be confirmed. Because of *rapid enlargement of the round shadow,* a pneumonectomy was performed. Examination of the surgical specimen disclosed a metastasis of a chorionepithelioma. On the basis of this diagnosis the urine was tested and a positive Aschheim-Zondek reaction and a positive melanophoric reaction were obtained. Subsequently other metastases appeared and the patient died. *At necropsy additional metastases* were discovered, but the testes were free from tumor tissue. The author cites other reports on extragenital chorionepithelioma in men and suggests that in the reported case the growth may have originated in a small retroperitoneal teratoma.

**Hypercalcemia in Besnier-Boeck's Sarcoid.**—Westra and Visser say that the literature of the last decade has repeatedly called attention to the occurrence of hypercalcemia in patients with Besnier-Boeck's disease. There is as yet no explanation for this concurrence. The authors cite the case of a young man with Besnier-Boeck's disease with hypercalcemia, increased phosphatase content of the serum and increased elimination of calcium in the urine. A surgically removed parathyroid, although free from granuloma, showed some hyperplasia. After the operation the calcium content decreased to normal values, but after five months it increased again. The authors feel that there is no argument for a direct connection between hyperplasia of the parathyroids and Besnier-Boeck's disease, but they believe that there might be an indirect connection.

Does Pregnancy Toxicosis Produce Residual Manifestations? J. L. Mastboom.—p. 176.
*Massive Deposits of Calcium Carbonate in Gallbladder. J. Glazenburg and H. J. Jongepier.—p. 186.

**Massive Deposits of Calcium Carbonate in Gallbladder.**—Glazenburg and Jongepier point out that massive deposits of calcium carbonate in the gallbladder were reported in the English language literature under the terms "limey," "milk" or "calcium" bile and in the German literature as "lime milk bile." They report the case of a woman, aged 53, who had had repeated gallstone colics during the weeks preceding her hospitalization. A stone which consisted largely of cholesterol and bilirubin was found at operation lodged in the cystic duct. On the side directed toward the gallbladder a rough white clump was found which consisted entirely of calcium carbonate. In the gallbladder was a whitish fluid which contained crystals of calcium carbonate and traces of calcium phosphate. There were signs of chronic infection and thickening of the bladder wall. The possibility of this disorder should be kept in mind in patients who have been treated with large doses of vitamin D and calcium, particularly if disorders of the gallbladder had existed before.

Epidemic Diarrhea in the New-Born: Review. A. Lichtenstein.—p. 1.
*Penicillin Treatment of Acute Osteomyelitis. K. Lind.—p. 2.
Can Rheumatic Polyarthritis Be Caused by Trauma? E. Jonsson and K. Berglund.—p. 7.
*Frontal Lobotomy in Chronic Psychoses. J. Elleberg.—p. 16.
Fistulas of Unknown Origin in Abdominal Wall in Syphilitic Patients. S. Baastrup Thomsen and Else Møller.—p. 21.

**Penicillin Treatment of Acute Osteomyelitis.**—Lind says that the results of penicillin treatment in acute osteomyelitis depend less on the dosage, provided it is over 100,000 units daily, than on the length of time of its application. Penicillin should be administered for two or three weeks (preferably for a week after the temperature is normal), so that the total dosage is at least 1,000,000 units. Surgical intervention can usually be avoided or limited to incision of larger abscesses. In case of intervention there should always be primary suture. Local treatment with penicillin has no certain beneficial effect. Intraosseous injection of penicillin into the focus seems to have many advantages and no harmful effects. Sulfonamide compounds administered simultaneously with penicillin are without demonstrable value but should perhaps be given, and in pneumonia doses, because of possible penicillin-resistant bacteria and because sulfonamide compounds seem to heighten the effect of penicillin. Immobilization should continue till the subjective symptoms have disappeared. The question of when weight bearing can be started must depend on roentgen examination three or four weeks after the start of the disorder. Movement should begin when the subjective symptoms allow. Sixteen cases of acute osteomyelitis in femur, tibia and humerus treated with *penicillin are reported.* In 3 cases the disease, inadequately treated, became chronic. In 2 cases in which treatment was apparently adequate, mild symptoms appeared one year and eight months, respectively, after the onset. Recovery resulted in 11 cases observed for eight to twenty-five months.

**Frontal Lobotomy in Chronic Psychoses.**—Elleberg reports on the results of bilateral frontal lobotomy in 43 patients from St. Hans Hospital for Women, observed for thirteen to twenty-three months after operation. Careful attention was paid to postoperative education. Of the 6 patients with manic-depressive psychosis 3 were discharged; in 2 the condition was unchanged, and in 1, aggravated. In 11 of the 34 schizophrenic patients the worst of the symptoms which indicated lobotomy had subsided completely; in 8 these symptoms had partially abated, and 15 did not improve. One patient with emotional instability was much improved and discharged, 1 with senile melancholia of paranoid kind was improved, 1 with psychasthenia was not improved. Six cases are described in detail. There was no postoperative deaths. One schizophrenic patient died during the observation period. Two patients had epileptic seizures. The results are considered satisfactory in view of the highly unfavorable prognosis in all cases, and lobotomy is being performed in similar cases.

*Succinic Acid Stimulating Respiration. M. R. Castex, L. E. Camponovo and F. E. Labourt.—p. 2083.

**Succinic Acid Stimulating Respiration.**—Castex and collaborators found that succinic acid, when injected intravenously, stimulates respiration and that this effect lasts two to forty-eight hours. They report observations on three groups of normal persons given intravenous injections of 5 cc. of a 1 per cent succinic acid solution (50 mg. of the drug). The effect on respiration was observed in two groups of persons in whom the functional tests of respiration were performed three minutes after the injection and again one hour later. In 7 patients in a state of anoxia due to disease of the respiratory tract, it was observed that the intravenous injection of the drug, stimulated respiration, as shown by the increase in the vital capacity, the complementary air and reserve of the air. This effect lasted for more than one hour. In a patient in the course of an attack of bronchial asthma the drug proved to have a constant stimulating effect on respiration which lasted for more than one hour and an antispasmotic effect on the bronchial musculature. Intravenous injection of 50 mg. of succinic acid into 9 persons in the course of provoked anoxemia caused diminution of the amplitude and frequency of respiration with a tendency to return to normal. Of 4 persons with normal electrocardiograms, the intravenous injection of 50 mg. of succinic acid produced a positive T wave in the precordial leads in 2 and in the second lead in 1. Of 13 persons with pathologic changes in the electrocardiogram, intravenous injection of 50 mg. of succinic acid caused an increased voltage of the T wave in the precordial leads in 9. The changes in the electrocardiogram after exercise were less marked after the intravenous injection of succinic acid in 3 of 6 patients with anginal syndrome and positive effort test. Electrocardiograms demonstrated that succinic acid injected intravenously provokes better utilization of oxygen by the myocardial fibers.

### 57:121-136 (Feb. 5) 1949

Criticism on Obesity from Retention of Water. E. Azerad and Berthaux. —p. 121.

*Autochthonous Malaria in France. L. Ferrabouc.—p. 122.

**Autochthonous Malaria in France.**—According to Ferrabouc, as a consequence of World War I cases of "autochthonous" malaria have been observed in France. Soldiers from Indo-China and workmen from North Africa have been the chief carriers. With World War II the incidence of malaria in France increased during the period of 1940 to 1946 and three recent "autochthonous" cases, one of them in the neighborhood of Paris, were observed in 1948. Primary inoculation with the plasmodia may be manifested by fever which continues on a fairly constant level for several weeks, the so-called invasion fever, which makes differential diagnosis from prolonged influenza, typhoid and typhobacillosis difficult in a country in which malaria is not endemic. Clinically suspected and confirmed by the laboratory, malaria is readily cured. For primary malaria of medium severity the following treatment is recommended: The patient is started on a treatment of attack with 2 Gm. of quinine daily for six days. He then is given 0.30 Gm. of quinacrine hydrochloride daily for five days, followed by 0.03 Gm. of pamaquine naphthoate N. F. for three days. Maintenance treatment for the following six weeks consists of 0.20 Gm. of quinacrine hydrochloride on three days within one week.

Limitations of Antibiotic Medication with Reference to Apoplectic Type of Cerebrospinal Meningitis. J. Cathala, R. Laplane, Contamin and Vasef.—p. 181.

*Psychotherapeutic Trial in Certain Pain Syndromes of Amputees. P. Padovani and M. Bachet.—p. 182.

Roentgen Ray Diagnosis of Disturbances of Cardiac Rhythm Related to Auriculoventricular Dissociation ("Block-Flutter-Ventricular Tachycardia"). R. Froment, A. Gonin, L. Gallavardin and P. Cahen. —p. 183.

Pathogenesis and Treatment of Premenstrual Syndrome. E. Juster. —p. 184.

**Psychotherapy in Pain Syndromes of Amputees.**—Padovani and Bachet applied psychotherapy to 13 amputees, all but 1 of whom had lost one of their lower extremities and had severe pain in the stump, which was not infected or mechanically defective. Psychic discomfort and the phenomenon of aging are closely connected with the pain of amputees. The emotive genesis of this pain is emphasized. It is different from psychogenesis the substratum of which may be reduced to an association of ideas of the unconscious. The patients were hospitalized; treatment was instituted seven days after the admission and was applied two or three times a week for two or three weeks. Therapy consisted in putting the patient in a state of perfect calmness, muscular relaxation and finally of complete psychic void. Five patients made a complete recovery; in 1 of them each attack of pain ended in a convulsive fit, and in 1 diabetes insipidus was associated with excruciating pain in the stump. The seizures as well as the polyuria disappeared. Two patients were improved considerably: sleep returned to normal, anxiety disappeared, emotivity was normal and severe attacks of pain ceased.

*Disobliterating Endarteriectomy in Treatment of Diabetic Arteritic Gangrene. R. Boulin, P. Uhry and Nogrette.—p. 3.

Case of Pleurisy with Transient Eosinophilia Associated with Labile Infiltration of Lung in Subclavicular Region of Same Side. L. Binet and H. Bour.—p. 11.

Treatment of Neuralgias of Extremities with Periarterial Procaine Hydrochloride Infiltration. B. G. Tsinoukas.—p. 12.

**"Disobliterating" Endarteriectomy in Diabetic Gangrene.**—Boulin and his co-workers performed a "disobliterating" endarteriectomy on 2 diabetic male patients aged 56 and 46, respectively. Extensive gangrene of the foot had resulted from trauma in the first patient with latent diabetic arteritis. Arteriography was the guide for "disobliterating" endarteriectomy. A longitudinal axial arteriotomy of about 12 cm. was made and heparinization was carried out during and after the intervention. Favorable results were demonstrated by postoperative control arteriography. In spite of the extent of the gangrene, tissue repair occurred within seven months. The second patient had arteritis with gangrene associated with severe pain. Arteriography permitted localization of thrombosis of the left iliac artery, and was a guide for "disobliterating" endarteriectomy. Excellent results were demonstrated on postoperative control arteriography. The unbearable pain subsided completely. "Disobliterating" endarteriectomy consists of the removal of the middle and inner coats of the artery in the obliterated segment and as far as possible in the parietal zones of the arteritis, while the elastic, healthy, outer coat with the adventitia is saved. Postoperative arteriography demonstrated absence of thrombosis in the segment operated on and absence of aneurysmal dilatation. "Disobliterating" endarteriectomy performed on patients of not too advanced age and in satisfactory general condition may make amputation unnecessary.

# Book Notices

**Surgery of the Hand.** By Sterling Bunnell, M.D., Consultant in Hand Surgery to the Surgeon General. Second edition. Cloth. Price, $16. Pp. 930, with 780 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C. 2, 1948.

A number of monographs on the surgery of the hand have been written by English, French and American surgeons, but none has approached in scope or comprehensiveness Bunnell's "Surgery of the Hand." The second edition of this unique contribution is enlarged by 200 pages, and contains many new and beautiful illustrations, some in color and many of them contributed by younger surgeons working under Dr. Bunnell's guidance and direction in the military hospitals designated as hand centers during the latter years of the war. No more convincing evidence could be produced of the value of the program that was evolved for the care of patients with injured hands, nor of the influence Dr. Bunnell exerted on his younger colleagues, than the many illustrations of the results obtained by Fowler, Frackelton, Graham, Howard, Littler, Macomber, Payne, Shaw and others of the younger men who took part in this extensive program and whose excellent results Bunnell has generously included among the illustrations in this new edition.

In reviewing a volume of such wide scope one can only point out a few of the changes and improvements that have been made. Chapter 5 on scar and flexion contractures has been enlarged from 65 to 104 pages, and many new and striking illustrations have been added. A discussion of local ischemic contracture involving the intrinsic muscles of the hand appears for the first time in this edition. Particularly in chapter 6 on bones, chapter 7 on joints and chapter 10 on intrinsic muscles of the hand and loss of the thumb, new material with many thought-provoking diagrams illustrating new and sometimes novel approaches to the problems involved in the treatment of the injured hand are presented. Methods of compensating for extensive injury to the bony framework by the use of grafts of cancellous bone, rib grafts, tibial grafts, transplantation of a metatarsal, shifting of an uninjured metacarpal to replace an adjacent hopelessly damaged metacarpal, bone block to provide fixed abduction of an injured thumb, new methods of repair of damaged extensor tendons—these and similar procedures indicate a few of the many problems that have been presented along with excellent illustrations of the results secured in their treatment.

The first edition of "Surgery of the Hand" was an outstanding contribution to surgical literature. In this new second edition the author has gone still further and added new and helpful ideas and suggestions and presented them with force and clarity. Every surgeon who is interested in the surgery of the hand will study it with profit and with interest.

**The Training of a Doctor.** Report of the Medical Curriculum Committee of the British Medical Association. Boards. Price, 7s.6d. Pp. 151. Butterworth & Co., Ltd., Bell Yard, Temple Bar, London, W.C. 2, 1948.

This is the official report of the Medical Curriculum Committee of the British Medical Association. Apparently, under a different system of medical education from ours they have come to the same problems. Thus they find that insufficient time is given to psychiatry and that the teaching given is inadequate, that there is insufficient recognition of the importance of social medicine, industrial medicine and public health and that there is a shortage of teachers in the basic medical sciences because it takes too long to get a medical degree before turning to specialization of this type. One must realize that the internship appeared in British medical education only in recent years. The British committee also places more stress on pediatrics than has previously been placed on this subject. There were majority and minority reports on pediatrics—the majority group insisted that pediatrics should be embraced by medicine and examination given as a part of examination in medicine, while the minority group believed that pediatrics should rank with medicine, surgery and obstetrics as one of the four major subjects in the curriculum. The report merits careful consideration by everyone interested in medical education.

**Voluntary Medical Care Insurance in the United States.** By Franz Goldmann, M.D. Cloth. Price, $3. Pp. 228. Columbia University Press, 2960 Broadway, New York 27, 1948.

According to the jacket of this work the book will answer two questions: 1. Is voluntary medical care insurance here to stay? 2. Will it eventually be made part of a broad national health program or succumb before legislation for compulsory health insurance? The book traces the history of voluntary insurance in the United States and the various methods of medical practice and concludes that voluntary medical insurance can serve selected economic groups only. Professor Goldmann is convinced that the idea of a nationwide program of voluntary medical care insurance is unrealistic, and he feels that in the long run the public will not be satisfied with prepayment plans which meet only a part of its total medical care needs and that physicians cannot be expected to be content with plans which disregard preventive services for the apparently healthy, do only half a job for the sick and impede the practice of psychosomatic medicine. He does see, however, in voluntary medical care insurance a chance to make real progress within its natural limitations and to help tens of millions of self-supporting people to lead personally satisfying and self-sufficient lives. The book fails to answer the question that it raises, whether or not compulsory health insurance will eventually take over voluntary plans. Apparently Professor Franz Goldmann is not yet ready to predict the ultimate fate of sickness insurance in the United States. He sees great danger from the use of federal funds to subsidize voluntary plans. His stature as a scientist rises by his avoidance of the attitude of soothsayer.

**The Parathyroid Glands and Metabolic Bone Disease: Selected Studies.** By Fuller Albright, A.B., M.D., Associate Professor of Medicine, Harvard Medical School, Boston, and Edward C. Reifenstein, Jr., A.B., M.D., F.A.C.P., Consultant-in-Charge, Department of Clinical Investigation, Sloan-Kettering Institute of Cancer Research, Memorial Hospital Cancer Center, New York. Cloth. Price, $8. Pp. 393, with 157 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

The work of the reviewer of this book is easy for two reasons: First, the authors themselves have included a critical review with the preface, and, secondly, the book is so outstanding that all a reviewer needs to do is to thank Drs. Albright and Reifenstein for having placed so much of interest in 400 pages.

Although the book is primarily intended for students of the subject, it will be read with profit by all physicians. It contains chapters on the normal and pathologic physiology of the parathyroid glands, clinical hypoparathyroidism, clinical hyperparathyroidism, the mode of action of vitamin D and dihydrotachysterol, general considerations of metabolic bone disease, with separate chapters on osteoporosis, osteomalacia, polyostotic fibrous dysplasia (osteitis fibrosa disseminata), and Paget's disease. In this book are considered all of the splendid advances which these authors and their associates have made in the understanding of the physiology and pathology of mineral and bone metabolism. There are excellent photographs and roentgen ray reproductions which illustrate the conditions under discussion.

There is an excellent appendix in which the authors' methods of analyzing and charting metabolic data are outlined; this is followed by a comprehensive bibliography and author and subject index.

This volume was doubtless written, first, because the authors wanted their thoughts on paper, but, more importantly, because physicians and scientists throughout the world were most insistent that these authors share their experience which has been so large and unique.

**The Shame of the States.** By Albert Deutsch. Cloth. Price, $3. Pp. 188, with illustrations. Harcourt, Brace, and Company, Inc., 383 Madison Ave., New York 17, 1948.

Recent years have seen exposés of the deficiencies of our state hospitals for the mentally disturbed. Such novels as "The Snake Pit" and "The Stubborn Wood" have focused public attention on the deficiencies in custodial and medical care. This book is certainly not a sober approach to its subject. It is a startling exposé in every way, from the language used to the pictures. Most of the American public became aware of the situation when *Life* magazine filled a whole section with similar pictures and legends. Already there are powerful movements toward improvement in the situation. However, the situation is bad not so much for lack of knowledge of its nature and scope as for inability to enlist sufficient public interest and public funds to bring about needed improvement. In his final chapter Deutsch says that not a single state mental hospital in the whole country meets all the minimum standards of care and treatment established twenty years ago by the American Psychiatric Association. He provides his own concept of an ideal state hospital, from entrance of the patient into the institution to his ultimate maximum improvement. Perhaps by error of the publisher there is a legend on a picture facing page 57 which calls attention to "a corner of a disturbed ward in which some forty patients were milling about in various stages of excitement or lethargy." The picture shows seven women, all of whom seem to be completely relaxed and perhaps most of them sound asleep.

**Methods of Psychology.** T. G. Andrews, editor. Cloth. Price, $5. Pp. 716, with illustrations. John Wiley & Sons, Inc., 440 Fourth Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W.C. 2, 1948.

The social science psychology is today in the stage of technical development that characterized some of the medical specialties in their period of growing pains. Often a field of science opens and broadens only after new instruments or technics have been invented and become applicable by great numbers of trained investigators. This might be said of the use of such instruments as the stethoscope and the electrically lighted instruments that are used in medicine or of the technics of Freud, Jung and Adler. The methods developed by the modern psychologists are already numerous and have begun to be applied not only in research but in practice in industry and education. The editor of this volume and the authors selected are recognized leaders in the field. The book will give to the physician and particularly to the workers in the field of psychiatry a good insight into the path by which psychology is advancing.

**Neurosurgical Pathology.** By I. Mark Scheinker, M.D., Assistant Professor of Neuropathology and Assistant Professor of Medicine (Neurology), University of Cincinnati, Cincinnati. Fabrikoid. Price, $8.75. Pp. 370, with 238 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Illinois; Ryerson Press, 299 Queen St., W., Toronto 2B; Blackwell Scientific Publications, Ltd., Oxford, England, 1948.

"Neurosurgery Pathology" is a nicely written and attractively printed monograph dealing with the central nervous system exclusively. The first 146 pages are devoted to the subjects of cerebral swelling and central nervous system injuries. Tumors of the central nervous system occupy the next 167 pages. The balance of the book contains briefer accounts of cerebral abscesses and hydrocephalus. A good bibliography and an index complete the book.

Dr. Scheinker, who is well known for his work in neuropathology, has made a distinct contribution by organizing many of his own concepts and presenting them in the form of a monograph for his readers. This not only should interest his colleagues in the field but should be of special value to the young man who is extending his studies in neurology in anticipation of making the field his specialty. Omission of a number of subjects usually dealt with in books on neuropathology has in no way detracted from the value of the present monograph.

**Acclimatization in the Andes: Historical Confirmations of "Climatic Aggression" in the Development of Andean Man.** By Carlos Monge, M.D., Sc.D., Director, Institute of Andean Biology, University of San Marcos, Lima, Perú. Translated by Donald F. Brown, Ph.D. With an introduction by Isaiah Bowman, President of the Johns Hopkins University, Baltimore. Cloth. Pp. 130. The Johns Hopkins Press, Homewood, Baltimore 18, Maryland; Oxford University Press, Amen House, Warwick Sq., London, E.C. 4, 1948.

Now that the airplanes take people to high altitudes, the value of the basic studies made by Monge and his associates in the Institute of Andean Biology is tremendously enhanced. The monograph is presented in good literary style, is well documented and will be fascinating to all who have seen at first hand the problem that this book considers.

**Crime and the Mind: An Outline of Psychiatric Criminology.** By Walter Bromberg, M.D., Senior Psychiatrist, Bellevue Psychiatric Hospital, New York. Cloth. Price, $4.50. Pp. 219. J. B. Lippincott Co., 227-231 S. 6th St., Philadelphia 5, 1948.

This book is the outcome of a seminar on psychiatric criminology at New York University. The case material is derived from New York courts and agencies of the Navy. The author has had complete cooperation in developing the material. It is submitted in two parts—first, the legal and social environment of the criminal and, second, the individual criminal. The book is designed for the trained workers in the field rather than for a popular audience. The case material is not extraordinary but of the type found all too frequently in psychiatric practice. Included among other important cases is that of Irwin, a brilliant young man who became schizophrenic and murdered several persons. It does not appear that modern mental hygiene could have done much to prevent or cure in the case of Irwin, but earlier detection and recognition of the possibilities might have avoided the ultimate catastrophe. The whole subject is now so great that it constitutes one of those specialties within a specialty that make modern medical education so difficult.

**The Psychoanalytic Reader: An Anthology of Essential Papers with Critical Introductions.** Edited by Robert Fliess, M.D. Volume I. Cloth. Price, $7.50. Pp. 392. International Universities Press, Inc., 227 W. 13th St., New York 11, 1948.

Here is a collection of papers in the field of psychoanalysis beginning with early essays in Vienna as far back as 1909 and others collected from the authoritative publications in the field since that time. Psychoanalysis is just about fifty years old. As science goes, that is exceedingly young. Like many other works in the field concerned, this one requires an almost completely unquestioning acceptance of all of the basic freudian doctrines. In no other field of true science is such unquestioning acceptance demanded.

**Cornell Conferences on Therapy. Volume III.** Edited by Harry Gold, M.D., and others. Cloth. Price, $3.50. Pp. 337. The Macmillan Company, 60 Fifth Ave., New York 11, 1948.

Maintaining the high standards of the previous volumes in this series, the present book will be a welcome addition to the library of the practicing physician. Among the topics considered by the authorities contributing to these conferences are the uses of streptomycin, uses of protein hydrolysates, treatment of pneumonia, treatment of hepatic insufficiency and management of pain due to muscle spasm. These subjects are ones of interest to almost all general practitioners. In addition, some excellent advice is presented on the rational use of cathartic agents.

The first chapter on "The Dose of a Drug" contains some controversial points in that the single dose method of digitalization is used as an illustration. If this is overlooked, many of the statements regarding drug dosage are excellent.

This volume has practical value for the physician, since it deals with commonly encountered clinical problems in therapy and discusses the rationale for the therapeutic measures recommended.

**Sex Habits of American Men: A Symposium on the Kinsey Report.** Edited by Albert Deutsch. Cloth. Price, $3. Pp. 244. Prentice-Hall, Inc., 70 Fifth Ave., New York 11, 1948.

The publication of the Kinsey report aroused a flood of essays and comments which approached the problem from many different points of view. The collection of essays included in this book is better than most because of the qualifications of the contributors. The work is certainly not one for the average reader, who is likely to come away from its reading more confused than if he had limited himself to Kinsey's original book. As might be expected, the Protestant, Catholic and Jewish points of view vary, and one wonders why a book of the type of the Kinsey book should be submitted to that type of study. The criticisms in the various chapters take the colors of the well established attitudes of the writers. If the reader has previously approached the subject he obviously colors what he reads by his own attitudes. If this seems confusing, it is.

# Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

## TREATMENT OF TICK BITE

*To the Editor:*—About the middle of May 1948 a 4 year old boy was bitten on the top of the head by a tick which presumably had come from his pet dog. Some fever developed and swollen masses behind the ears. The day following the bite the parents left for Oklahoma, and while there called in a physician who found that the boy had a high grade fever. He was given four daily injections of penicillin; the amount of each dose is not known. On his return from Oklahoma he was brought to me; this was about two weeks after the original injury. The patient then seemed to feel well, and the mother reported that she had been unable to discover any elevation of temperature. Several small spongy masses in the back of the neck and the scalp were not tender, but were soft, and presumably were the postauricular lymph nodes. He was placed on small doses of sulfadiazine for two or three days and was not seen until about six weeks later. At this time the bite on the top of the head was practically healed but had still a small crust present. The lump behind the left ear was inflamed and showed indications of a small amount of fluid beneath the skin. Presumably this cleared up rather promptly, since he was not seen again until September 10, when he came in with a flare-up of an old impetigo around the mouth and on the chin. This cleared up promptly under appropriate treatment, but on September 17 he came in with cellulitis of the throat, which went on to abscess formation and was lanced and drained four days later. This healed without further complications. The child returned this morning with a small pustule behind the left ear overlying the mastoid bone, where he previously had swelling which was secondary to the tick bite. This has a small crust on it and appears likely to drain promptly and without further complications, since there is no inflammation surrounding it. The site of the tick bite on top of the head is still visible, and the small round scar appears to be entirely healed. Are recurrent episodes of this sort common after tick bites?

Ray S. Wycoff, M.D., Lexington, Neb.

[This inquiry was referred to two authorities, whose respective replies follow.—*Editor.*]

ANSWER.—Probably the tick involved in this case was the American dog tick, Dermacentor variabilis, since that is the species most commonly found in that portion of Nebraska. This tick is the principal transmitter of Rocky Mountain spotted fever in the Central and Eastern parts of the country and it has also been involved in the transmission of tularemia and in the causation of tick paralysis. Obviously neither Rocky Mountain spotted fever nor tick paralysis was involved in the present case, and it is doubtful whether it was tularemia. It is difficult to explain the persistent and recurrent sequelae. Secondary infection from tick bite is not unusual, and frequently itching and soreness at the point of attack persist for weeks or even months after the tick has been removed. This is particularly true of species of ticks having long mouth parts, such as the "Lone Star" tick. It is less frequent when the American dog tick is involved. The persistence and recurrence of infection in this case suggest that some organism was introduced by the tick at the time of the bite. To prevent infections from tick bites, some have suggested the application of a cauterizing agent at the exact site of the bite, particularly if this treatment can be given immediately after the tick is removed. The tick should be removed as soon as possible to avoid both infection by Rocky Mountain spotted fever and possible tick paralysis. This also reduces the chances of the persistent annoying effects of the bite, which appear to be associated with the introduction of saliva or other secretions of ticks.

ANSWER.—The early symptoms and the history of a tick bite suggest a mild case of ulceroglandular tularemia. If so, the organism probably is no longer present. The agglutination test, if positive in result, would tend to confirm a diagnosis of tularemia. Recurrence of inflammatory lesions of tularemia is not expected after apparent cure.

The subsequent impetigo followed by cellulitis of the throat and an abscess under the chin may have been caused by ordinary pyogenic bacteria. Cultural examination of material from an active lesion would be helpful in determining the organism which is active at present. Adequate treatment with a suitable sulfonamide compound or antibiotic probably would hasten healing and prevent recurrence.

Excellent results in the treatment of ulceroglandular and other forms of tularemia have been reported recently by the following observers: Bost, Percefull and Leming (J. A. M. A. **137**:352 [May 22] 1948); Foshay (*J. Indiana M. A.* **41**:207 [Feb.] 1948; abstracted J. A. M. A. **137**:1158 [July 24] 1948); Morgan (*Ann. Int. Med.* **27**:487 [Oct.] 1947; abstracted J. A. M. A. **136**:350 [Jan. 31] 1948); Johnson, Wilkinson and Figueras (*Am. J. M. Sc.* **214**:645, 1947); Berson and Harwell (*Am. J. M. Sc.* **215**:243 [March] 1948; abstracted J. A. M. A. **137**:1622 [Aug. 28] 1948), and Lesser and Miller (*New England J. Med.* **238**:554, 1948).

Berson and Harwell observed that streptomycin therapy of tularemia appears to have little effect when administered after the twelfth day of illness. Good but less rapid improvement was attributed by Curtis and Park (J. A. M. A. **113**:294 [July 22] 1939), to sulfanilamide and to quinacrine by Ecke and Ecke (abstracted J. A. M. A. **138**:775 [Nov. 6] 1948).

## CHRONIC MONILIASIS

*To the Editor:*—What is the treatment for chronic recurrent oral moniliasis?

C. L. Concklin, M.D., Corpus Christi, Texas.

ANSWER.—Specific therapy for moniliasis is not known. Human infection by this fungus is usually considered to occur in locus minoris resistentiae. It should therefore be possible to use a routine which will clear the mouth infection (thrush) and prevent its recurrence. It should be ascertained that the infection is strictly oral and that the subject is not diabetic. It is unfortunate that the extent of infection, the general condition and the previously used therapy are not mentioned. Local sites, including gingival crevices and poorly fitting dentures, should be cared for. Foci elsewhere on the body (skin, vagina, under the nails) should be cleared to prevent reinfection. The tongue may be scraped to rid the surface of ancient filiform papillae.

Some authorities feel that the predisposing cause is a vitamin B deficiency. Injections of a B complex concentrate, followed by the use of oral doses and attention to the diet, are worth while. Simple local measures are usually enough to clear the tongue lesions, and continued use should prevent recurrence. D. T. Smith has advised a bland alkaline mouth wash (10 per cent sodium bicarbonate) several times a day, or a wash of 1 to 10,000 gentian violet. Acriviolet® (containing acriflavine, crystal violet and methyl violet 2B) and ferric chloride are also effective. McKee and Cipollaro suggest applying 2 per cent aqueous gentian violet once a day. Roentgenotherapy may be used for severe unresponsive lesions. An autogenous rabbit serum vaccine has been reported to clear cases of resistant disease in which results of skin tests are positive, a daily subcutaneous hyposensitizing technic being used.

## NITROGEN MUSTARD IN CANCER

*To the Editor:*—What is the therapeutic effect of nitrogen mustard on highly cellular carcinoma or lymphoblastoma?

J. S. Collins, M.D., Wabasha, Minn.

ANSWER.—The nitrogen mustards have been found most useful in the palliative treatment of malignant lymphomas. Such treatment has effected temporary remissions in cases of Hodgkin's disease more consistently than in cases of the lymphosarcoma group. Results in the treatment of metastatic carcinoma have been uniformly disappointing. The effects observed are, generally speaking, similar to those following irradiation therapy but have been less consistently favorable and the resultant remissions of somewhat shorter duration.

While great reduction in size of a neoplastically diseased lymph node following nitrogen mustard therapy might be considered evidence favoring a diagnosis of malignant lymphoma rather than metastatic carcinoma, biopsy study would still be necessary for positive diagnosis.

## HEMATURIA OF UNKNOWN ORIGIN

*To the Editor:*—A male patient's urine repeatedly shows 2 to 3 red cells per high power field. Dr. A. states that the urine should be checked every month and, if there is not an increase in number of cells, this finding can be disregarded. Dr. B. states that after two or three samples of urine have consistently shown this finding the patient should be studied to determine the source of the cells, cystoscopy and pyelography being used if necessary. Which is correct?

M.D., Connecticut.

ANSWER.—The number of red blood cells found in the sediment of centrifuged normal urine varies between individuals and with the concentration of the sediment; however, 2 or 3 cells per high power field is abnormal and should be explained. The diagnosis of hematuria of unknown origin should be made by exclusion and accepted with reluctance. The three glass urine test, collecting urine at the start, during and at the end of urination would be useful, but cystoscopy, ureteral catheterization and pyelography are certainly indicated in order to ascertain the source of the hematuria.

### ORAL LESIONS AFTER HYSTERECTOMY

*To the Editor:*—What lesions are found in the mouth after hysterectomy? The buccal mucous membranes of a patient's mouth have blisters and white fibrous lines of scarred tissue at the center of the lesion extending posteriorly. Her chief complaint is that the saliva feels thick and ropy. This condition has not responded to hormonal, vitamin or liver therapy. What is the diagnosis and treatment? M.D., New York.

ANSWER.—Oral lesions directly due to simple hysterectomy are not known.

Indirect results might follow anesthesia, an associated oophorectomy, the presence of an infection, dehydration or an autonomic imbalance. The cause could be assessed better if data on the operation, general condition and age were given.

The best explanation would seem to be trauma to the buccal surface, on a line of the dental occlusion, due to the procedures of anesthesia, plus oligosialia.

A return to good general condition and hydration should clear both conditions, but if it does not it has been recommended that a few days' trial of neostigmine bromide, ½ tablet (7.5 mg.) by mouth after each meal, will result in profuse salivary secretion and clearance of the oral lesions. Omit drugs which decrease secretions (belladonna, etc.), and use a soothing dilute mouth wash.

### MÉNIÈRE'S SYNDROME

*To the Editor:*—A married, childless, 56 year old white American bank teller has had slight dizziness for the past two years, lasting a few moments at a time to full blown attacks of dizziness so bad that he would fall to the ground unless supported. Intense pallor, cold sweat, nausea and vomiting occur with these attacks. After a few hours of bed rest he improves and is able to work though it takes about two days to recover completely. About two years ago the patient's first attack came on so suddenly that he was unprepared and fell to the ground. Later when he got used to the attacks he could hold himself up by hanging on to some support. At about the same time that these attacks began he discovered that he was totally deaf in the left ear. At times the dizziness strikes him so that objects and walls of the room all roll about in a hopeless jumble; he staggers about in an incoordinated manner though his legs do not buckle. He falls because of incoordination and lack of balance. His physical examination does not reveal any abnormality. He has worn bifocals since age 16. His blood pressure is 130 systolic and 80 diastolic. Roentgenograms of the skull do not reveal abnormality. Is Ménière's syndrome the logical diagnosis? What further tests should be performed and what is the treatment? M.D., New York.

ANSWER.—The diagnosis of Ménière's syndrome in your case is not only a logical one but an accurate one. Your case is associated with pseudoapoplectic or pseudoepileptic types of seizure together with deafness in one ear. Has your patient any tinnitus aurium? If he is totally deaf in the involved ear there will not be noises or tinnitus. Is the tuning lateralized on the skull? In order to clinch the diagnosis it is suggested that you have a skiagraphic study of the internal auditory meatuses made. A cerebellopontine angle tumor may produce these symptoms. The most practical and efficient therapy in your case is the giving of phenobarbital in doses of 1½ grains (0.1 Gm.) two, three or four times daily. You must tell your patient to be careful about moving his head, because such movements will invariably result in an attack of labyrinthine vertigo. This is especially true in the morning when the afflicted person wakes up and jumps out of bed. It is entirely possible and practical to do this, and your patient will be everlastingly grateful to you. The salt-free diet and other forms of dietary regimen have been unsuccessful. You could have your patient undergo an intracranial section of the vestibular or cochlear nerve on the left side. This, however, is not to be done if you can stop his vertiginous attacks with phenobarbital. Certainly if he is not troubled with tinnitus such an operation is not indicated. He must take his medicine constantly for many years.

### HUMAN PARTHENOGENESIS

*To the Editor:*—Is there any authentic evidence aside from religious records, excluding of course the possibility of accidental cell union in both tubs or female intimacy, that both male and female cells have been found in a person, as an aberrant type of human parthenogenesis or uterine or extrauterine fetal development, teratoma in type? Has there been evidence of a fetus developing from such embryonic cells and if so what stage of fetal development has been reached?
Clarence W. Lieb, M.D., Rancho Santa Fe, Calif.

ANSWER.—"Fatherless" rabbits have been produced by obtaining the unfertilized ova from a female rabbit, stimulating the initiation of development by glass needle or other means and then, when development has begun, transplanting them into the tubes of another virgin rabbit.

In the case of the human ovum, unfertilized ova have been obtained from the tubes of women who have been operated on for fibroids or other pelvic conditions. They have been placed in culture mediums and development has been started, but up to the present experiments have not been recorded in which these parthenogenetically initiated ova have been transplanted.

Since the possibility of this type of development has been established, at least in its beginning, it is a fair assumption that such growths as teratomas which appear in the ovaries bear relation to the hostess as offspring to mother. The other theory has been that there may be a totally potent cell segregated early so that the relationship is as of twins.

### NEGATIVE T WAVE IN LEFT UNIPOLAR LEAD

*To the Editor:*—Would you please discuss the meaning of a negative T wave in the left unipolar arm lead in the electrocardiogram? If it is at times normal, how would you differentiate a normal negative T wave from an abnormal one? If a negative T wave in an $aV_L$ lead is always abnormal, then $T_3$ greater than $T_1$ must be considered abnormal. M.D., Ohio.

ANSWER.—The deflection in the unipolar left arm lead at a given instant is equal to the simultaneous deflection in lead I minus the deflection in lead III. Inversion of the T in this lead means, therefore, that the T wave in lead III is larger than the T wave in lead I. This situation occurs normally when the heart is in the vertical position, in which the potential variations of the two arms are similar and like those at the base of the heart. When the ventricular deflections in the two unipolar arm leads are alike, inversion of the T wave in the left arm lead has no significance. In this case the chief QRS deflection in both of these leads is downward. Inversion of the T wave in the unipolar left arm lead when the chief QRS deflection is a relatively large R wave is usually, if not always, abnormal. If such findings are accompanied by a Q wave which is more than one fourth the size of the R wave which follows it, precordial leads should be taken to rule out anterior infarction. In rare cases of this kind, there is a high lateral infarct, and it is necessary to take precordial leads from points between the standard ones and the left shoulder in order to obtain tracings that are diagnostic of infarction. Such tracings are significant only when they show changes more characteristic of infarction than those in the usual precordial leads and also more characteristic than those in the left arm lead.

### PAROXYSMAL LABYRINTHINE VERTIGO

*To the Editor:*—A number of elderly women and an occasional elderly man complain persistently of "disturbing dizziness" or "noises in the head" or "headache" which moves from place to place at intervals during the day over a protracted period. Most of these patients give evidence of arteriosclerotic changes elsewhere in the body, and many of them have hypertensive cardiovascular disease. Is there a satisfactory therapeutic agent for these patients? If so, could you indicate the physiologic basis of action as well as the name of such agents. Hypotensive agents such as mannitol hexanitrate and veratrum viride have been unsuccessful. Tincture of belladonna, amphetamine sulfate, phenobarbital and other sedatives or stimulants have failed to give satisfactory results. I have not tried testosterone or vitamin E, both of which have been said to have vasodilating actions. M.D., Massachusetts.

ANSWER.—Your patients are afflicted with paroxysmal labyrinthine vertigo or pseudo-Ménière's syndrome. This is true only if your patients fail to show objective evidence of brain tumors or other lesions. From your description they have a sclerotic lesion in the vestibular and cochlear systems. The only drug that has proved valuable in our cases is phenobarbital. It must be given in proper doses. These are 1½ grains (0.1 Gm.) two to four times daily. Your patients may become drowsy, but this will be accepted in a more wholesome manner than the terrific attacks of vertigo. Other forms of treatment have not helped. Advise them to be extremely careful about moving their heads because such movements invariably start an attack. If the noises and headaches are severe (and phenobarbital will not relieve them), it is suggested that you think of advising your patients to have an intracranial section of the involved vestibular and cochlear nerves. If you can control the vertigo this operation should not be done.

### ENCEPHALITIS DUE TO MEASLES

*To the Editor:*—Is encephalitis rarer after modified measles than after unmodified measles? M.D., New York.

ANSWER.—Encephalitis is a rare complication of unmodified measles. Nervous symptoms occur in about 0.5 per cent of all cases of measles. Modified measles are naturally less frequent than unmodified measles and usually run a much milder course with fewer complications. References to the incidence of encephalitis following modified measles are not known.

# BENIGN TUMORS OF THE BREAST

HARRY C. SALTZSTEIN, M.D.
Detroit
and
ROBERT S. POLLACK, M.D.
San Francisco

There are, perhaps, few conditions which cause as much anxiety and worry to the patient as do tumors of the breast. The reasons are not simple or clear. The breast is, of course, the most superficially placed of all organs where cancer frequently occurs, but there are deep psychogenic reasons which make the thought of loss of the breast terrifying to the average woman.

Five years ago, in our personal practice, we operated on as many cancers of the breast as we did on benign lesions of the breast. For the past three years, our operative records show twice as many benign tumors as cancers. In addition, the number of breast conditions seen and not operated on now almost equals the number in which there was surgical intervention (table 1). We also noticed that the number of patients with breast conditions seemed to increase during and immediately after periods of publicity regarding cancer. Public education in cancer seems to focus on a lump in the breast.

From the physicians' point of view, the problem in dealing with tumors of the breast is accuracy in diagnosis. Leach and Robbins[1] found that 50 per cent of patients in their series with mammary tumors received "improper advice," and Haagensen[2] in a similar compilation found that 27 per cent had been given "wrong medical advice."

## MATERIAL AND HISTOLOGIC TYPES OF BENIGN TUMORS

A large part of the problem in cancer of the breast is the separation of various benign tumors from the malignant ones. We have reviewed the last 100 consecutive cases of benign tumors of the breast seen by us, our interest being chiefly in the diagnostic problems and indications for treatment. All 100 patients had microscopically proved diagnoses.

In table 2 are listed the histologic types of conditions encountered. Half (50) of the patients had chronic cystic mastitis; 26 had adenofibromas and 7 had lipomas. There were 12 papillomas, 6 intracystic and 6 in the lacteal ducts. There were only 3 abscesses, but in 2 of these draining sinuses persisted until they were completely excised. Only 1 patient was observed with fat necrosis, which had followed an injury. In 1 patient a well localized tumor was removed from the tail of the breast and found to be aberrant mammary tissue. There were 2 male patients; one had a lipoma and the other an abscess.

During 1947, 26 patients with benign tumors underwent surgical intervention. At the same time 22 patients were observed with conditions of the breast that for various reasons did not require operative procedures (table 1). Nine of these complained of pain only, and *nothing was discernible on examination.* Four patients had had previous surgical operations, and the microscopic diagnoses had been chronic cystic mastitis. Although a diffuse nodularity was felt in the breast of each patient, another operation was not deemed necessary. Five patients presented solitary mammary cysts, which were aspirated and then disappeared completely. Of the 4 remaining patients, in 1 a nodularity which had been felt on her first visit disappeared within five months. In another, a small mass near the areola papillaris persisted. The remaining 2 patients failed to return. The presumptive diagnoses were chronic cystic mastitis.

## CHRONIC CYSTIC MASTITIS

In 33 of the 50 patients with chronic cystic mastitis (table 2) the disease was most pronounced in the upper outer quadrant of the breast. Nine of the 50 had bilateral disease on their first visit, all but 2 of these in the upper outer quadrant of each breast.

This disease by its very nature pathologically is of long duration (except for the isolated acute cases), but due to an enlightened public its clinical course as we now see it is becoming much shorter. Nineteen of the foregoing patients sought medical advice within the first two weeks after they noticed symptoms, 27 within the first month and 8 more within three months after the onset of symptoms. In only 5 were symptoms present longer than one year without their having sought medical aid (1 of these for ten and 1 for sixteen years). It is evident that we no longer have the comforting words, "my breast has been bothering me for years," as an aid in diagnosis.

Twenty-nine patients were between the ages of 40 and 49, and 13 were between the ages of 30 and 39. As these figures illustrate, chronic cystic mastitis is most frequently observed in women at or just before the menopause, when the endocrine balance is beginning to readjust itself to a new level. Of the 29 patients between the ages of 40 and 49 who had this disease, 10 complained of menopausal symptoms and another 5 had other gynecologic disorders; fibromyomas of the uterus, menorrhagia, scanty menses and cervical polyps.

Pain was present in half (26) of the patients. In 11 it was the initial symptom, and in 15 it developed as the condition progressed. Pain is not a common

---

From the Surgical Department, Harper Hospital.

Dr. Pollack is now Director of Tumor Service, United States Marine Hospital, San Francisco.

[1] Leach, J. E., and Robbins, G. F.: Delay in the Diagnosis of Cancer, J. A. M. A. **135**: 5-8 (Sept. 6) 1947.

[2] Haagensen, C. D.: Carcinoma of the Breast, J. A. M. A. **138**: *195-205* (Sept. 18); *279-292* (Sept. 25) *1948.*

symptom of mammary cancer (about 10 per cent of cancer patients have pain), and on the basis of this small series many highly excited and distracted patients, convinced because of pain that they have cancer, can be reassured.

In 33 patients the first sign of chronic cystic mastitis was the presence of a lump in the breast. On examination a diffuse nodularity, which was slightly tender, could be felt in half of the patients. Except for the solitary cysts no single tumor could be palpated, but instead there was a poorly outlined, thickened, irregular mass, which in some patients appeared to be composed of multiple small cysts and large, thickened cordlike lobules. On palpation these tumefactions seem to be part of the breast tissue itself and do not move freely. In 3 of our cases there was retraction of the overlying skin with slight pulling of the nipple (fig. 1). Therefore, retraction of the skin is not an invariable sign of cancer.

Table 1.—*Number of Patients Seen During Past Five Years with Benign and Malignant Tumors of the Breast*

| Year | 1943 | 1944 | 1945 | 1946 | 1947 | Total |
|---|---|---|---|---|---|---|
| Malignant | 8 | 18 | 7 | 10 | 11 | 54 |
| Benign | 8 | 20 | 26 | 20 | 26 | 100 |
| Presumably benign, unoperated (one year only) | .. | .. | .. | .. | 22 | 22 |

## CHRONIC CYSTIC MASTITIS AND CANCER

The relationship of chronic cystic mastitis to cancer has varied widely among different investigators. Ackerman and del Regato[3] stated that it is "directly proportional to the liberality of the pathologist in diagnosing such a lesion." Foote and Stewart[4] similarly have stated that "the concomitant occurrence of cancer in so-called chronic cystic mastitis will vary statistically according to the selection of lesions."

By and large, pathologists have agreed that the microscopic changes of small cyst formation and proliferation of the epithelium occur in a large percentage of cases of cancer of the breast. MacCarty and Mensing[5] found 100 per cent of 967 carcinomas of the breast associated with chronic cystic mastitis. Ewing[6] reported at least 50 per cent; Semb,[7] 80 per cent. Cheatle[8] repeatedly emphasized the association of cancer and chronic changes in the breast.

Table 2.—*Histologic Types of 100 Consecutive Benign Tumors of the Breast*

| | |
|---|---|
| Chronic cystic mastitis | 50 |
| Unilateral | 41 |
| Bilateral | 9 |
| Papillomas of the duct | 6 |
| Intracystic papillomas | 6 |
| Adenofibromas | 26 |
| Lipomas | 7 |
| Abscesses | 3 |
| Fat necrosis | 1 |
| Extramammary tissue | 1 |
| Total | 100 |

Pathologists have differed with regard to the direct etiologic relationship of these changes to carcinoma. Ewing[6] and Warren[9] both used the term precancerous and thought that epithelial hyperplasia preceded cancer in enough instances to be significant. However, Foote and Stewart,[4] after an exceedingly careful and critical analysis of 200 cancerous and 300 noncancerous breasts, found that the changes described in chronic cystic mastitis are just as common in noncancerous as in cancerous breasts. They further state that it has not been proved that these changes are the focal starting points for cancers of the breast in any sufficient number to be significant.

The confusion exists in the criteria which different pathologists use to diagnose chronic cystic mastitis. In Foote and Stewart's material 59 per cent of the patients with cancer of the breast exhibited one of five cystic and proliferative lesions; cysts, papillomatosis of the duct, blunt duct adenosis, sclerosing adenosis or apocrine epithelium. Sixty-five per cent of 200 noncancerous breasts likewise contained one of these five features. When two or three of the foregoing features were tabulated in the two groups, the difference between the cancerous and the noncancerous breasts was not outstanding, and the etiologic relationship of chronic cystic mastitis to cancer was not proved.

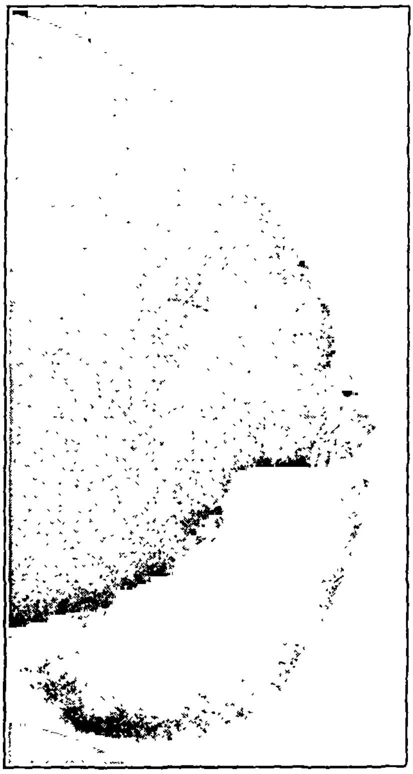

Fig. 1.—Dimpling of skin caused by small cyst close to the surface of breast. The scar lateral from the nipple represents local excision of area with chronic cystic mastitis on March 20, 1947. One month later the small thickened area (marked with a cross) was noticed 1 inch above the nipple. A small amount of yellowish fluid was obtained on aspiration. The indurated area persisted and therefore a second local excision was done May 10, 1947. A small cyst with smooth lining was removed.

As the foregoing statements would indicate, there has been a steady tendency to regard these lesions as not necessarily leading to cancer. Starting with Bloodgood,[10] then White,[11] Lewis and Geschickter[12] and, more recently, Foote and Stewart, to mention a few authors, the realization has grown that present information is not conclusive enough to state with exactness the precancerous nature of this lesion. Nevertheless, in clinical follow-up studies a certain small but significant relationship must be admitted to exist. Many series have shown this. Warren[9] in a careful and extensive clinical study followed 1,206 patients with chronic cystic mastitis. Cancer developed in 42, or about three times the incidence expected in the normal population. More concretely, between the ages of 30 and 49, women with chronic mastitis have 11.7 times greater incidence of cancer. After 50 years of age the incidence is 2.5 times greater. It is still believed, therefore, despite the lack of anatomic evidence, that the proliferative lesions of chronic cystic mastitis predispose toward a slightly higher incidence of cancer.

Clinically, one may describe three broad groups of patients with this disease. One group includes those patients with blue dome cysts. Bloodgood[10] was the first to state categorically that these had no relationship to cancer. The cysts occur in the age group of the menopause, often in women with soft full breasts, and arise suddenly with some associated pain. They are usually discrete, single and tense.

During the time of this study we have aspirated nine cysts (not included in table 2), most of them during the past year. As a rule 10 to 20 cc. of turbid yellow or greenish fluid, often under pressure, was obtained. Usually this was all the treatment that was necessary, and after two or three weeks the breast tissue felt smooth and normal at the site of the aspiration. In 1 case the first aspiration was unsuccessful but the second, performed under anesthesia and with the patient prepared for local excision, brought forth 30 cc. of greenish turbid fluid under tension from two separate cysts. Nothing further was done, and the breast felt normal in a few weeks. Two cysts refilled within two weeks, and therefore local excision was immediately performed. Two other patients had small localized areas of residual induration which remained for three weeks after aspiration, and excision was therefore performed.[13]

We consider that aspiration of a simple cyst (fig. 2) is a safe procedure, provided the patients are carefully selected and both physician and patient are prepared for excision of any residual localized or indurated mass that does not subside after a few weeks. In 2 patients the attempt at aspiration was unsuccessful. Both were advised to return for a recheck and probable excision but did not do so.

Another group which is sometimes separated includes young women who complain merely of pain in the breast and on examination exhibit tender, firm, diffusely thickened areas most commonly found in the upper outer quadrant. These have been called painful breasts, mastodynia or mazoplasia; all terms which indicate a mild condition. Reassurance of the patient is all that is necessary, and further treatment is not required. During the past year, of the 22 patients with breast complaints who did not come to operation, 9 complained only of pain and belonged in this group.

The third and largest group, and the one wherein so much confusion exists, is probably a more exaggerated or later form of the mastodynias. This condition is called variously Schimmelbusch's disease, benign parenchymatous hyperplasia, adenosis, adenocystic disease and a variety of other names. These women are often childless, are in their late thirties or early forties, have irregular menses and are nervous and underweight. A frequent association with thyroid and uterine tumors may be found. They often have small, dense, saucer-edged breasts with multiple nodules on palpation. Microscopically, the mammary tissue is characterized by minute cysts of various sizes, usually smaller than 0.5 cm. and with varying epithelial proliferation. Most of the local excisions that were performed were on patients whose disease fell into this group.

FOLLOW-UP

Thirty-five of the 50 patients on whom we performed local excision for chronic cystic mastitis were followed for six months or more. Nine still complained of pain and nodularity in the breast, and in 3 of these definite cystic areas were felt at varying intervals.

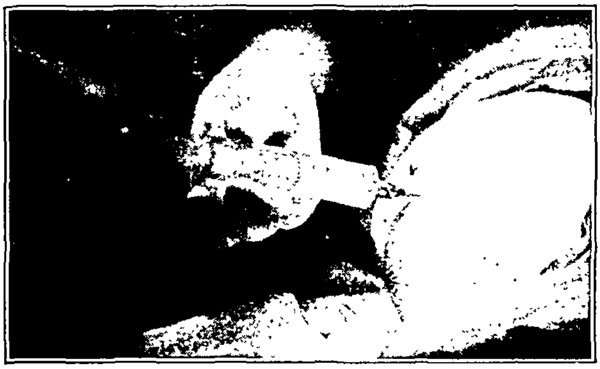

Fig. 2.—Aspiration of a blue dome cyst.

Chronic cystic mastitis is a disease of all the mammary tissue, and it is obvious that local excision is not curative. Surgery is performed primarily to rule out cancer. Statistical evidence which shows an increased (3 to 5 per cent) liability to form cancer in these patients is a secondary consideration.

PAPILLOMAS OF THE DUCT

There were 6 patients in whom a serosanguineous discharge was caused by a papilloma in the lacteal ducts. Bleeding from the nipple was present for as short a time as one week and as long as three years. Bleeding may start from a slight trauma or spontaneously, and it may continue daily with the passage of a few drops or intermittently every one or two months. In some this symptom may become more persistent at the time of the menopause. The youngest patient was 36, the oldest 52.

In all 6 cases local excision of the papilloma of the duct with a small margin of surrounding mammary tissue was performed. The papillomas were microscopically benign and ranged from 2 to 10 mm. in diameter. Mastectomy is not necessary for this condition. Once the cause of bleeding is identified as a papilloma (fig. 3), its complete excision carried out and its benign character verified, the risk of subsequent formation of cancer in the same breast does not warrant radical amputation (Saltzstein and Pollack[14]).

[13] It sometimes takes six to eight weeks for the breast to feel normal again.

Six intracystic papillomas (within small cysts in the parenchyma of the breast) were found in the pathologic examination of specimens removed from those patients with chronic cystic mastitis. These are not included in the 50 cases of chronic cystic mastitis already described. It emphasizes the fact brought out by Foote and Stewart[4] that papilloma formation is not uncommon in this condition. It is one of the features of the disease. There were no distinguishing clinical signs or symptoms in this small group of 6 patients to set them apart from the remainder of the patients with chronic cystic mastitis. None had bloody discharge from the nipple, and all sought medical aid because of a mass in the breast of from one week to two years' duration. In 3 the mass was tender. All were treated by local excision of the localized area of chronic cystic mastitis.

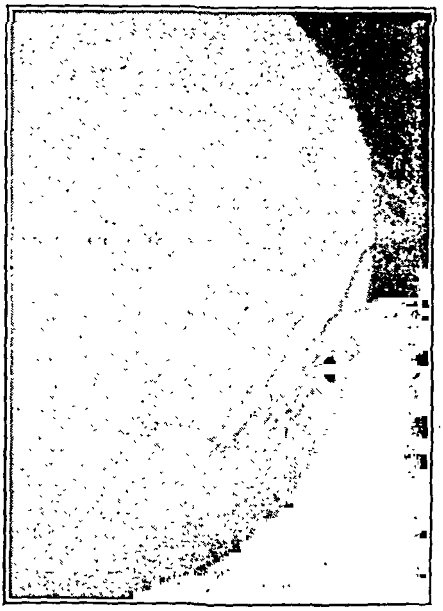

Fig. 3.—Roentgenogram of the breast following injection of lacteal duct with methiadol sodium (skiodan®). A large papilloma is seen filling the duct, starting 1 cm. from the orifice of the duct.

ADENOFIBROMAS

There were 26 adenofibromas in the 100 cases. This tumor has several distinctive characteristics; hence, diagnostic difficulties are considerably less than with chronic cystic mastitis.

As with other types of mammary tumors, the upper outer quadrant was most commonly the site. Fourteen adenofibromas were in this region. In 22 of the 26, the first symptom was merely the presence of a lump in the breast. In only 4 instances was any pain associated with the tumor. Twenty-one tumors were described as freely movable, well outlined and firm without tenderness. The remaining 5 were thought to be poor in outline, diffuse and with some softness. Only 2 of the 5 were tender.

Eleven patients consulted a physician within the first month and 7 more within the first six months. Two patients had had the tumor fifteen and thirty years, respectively, but had done nothing about it because, "it did not bother them." Both tumors were locally excised and revealed no evidence histologically of any change to a more anaplastic type of growth.

In 18 patients, or 72 per cent, the tumors occurred between the ages of 20 and 39; in 7 between the ages of 40 and 49; extreme ages were 20 and 48 years. None of the patients were pregnant and none past the menopause, although 8 per cent in Geschickter's series[15] were beyond the menopause and in 10 per cent the tumors were present before the first menses.

Eight patients had associated gynecologic complaints. Three had fibromyomas of the uterus, one of them having a thyroid adenoma as well. Three had menstrual irregularities and 2 were experiencing symptoms of the menopause. The relation of this tumor to periods of estrogen stimulation has been commented on by several authors.

Adenofibromas occur predominantly in women of the child-bearing period. The tumors are liable to rapid growth during pregnancy and also when they occur at the time of the menopause. This is reason enough for early local excision. In addition, malignant degeneration is not uncommon. Of 29 sarcomas of the breast collected by Geschickter,[15] 11 were thought to have formed from preexisting adenofibromas. Adair and Herrmann[16] collected 30 sarcomas and believed that 4 were from previous adenofibromas. Cystosarcoma phylloides (giant intracanalicular fibromyxoma, giant mammary myxoma) is an old term denoting a large, slowly growing, solitary tumor of the breast, previously considered to be benign. It is now commonly believed that these tumors also arise from preexisting adenofibromas and may become cancerous. In a recent review of 52 of these cases by one of us (R. S. P.),[17] 8 were found to be cancerous and the patients had a rapidly fatal course.

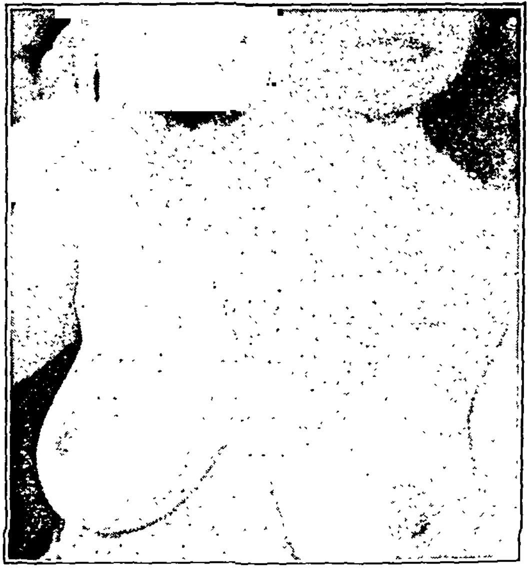

Fig. 4.—Accessory breast tissue.

MISCELLANEOUS TUMORS

Seven of the 100 patients had lipomas. These are completely innocent tumors, but their presence alone may cause much worry and anxiety. It may be difficult to be certain that they are only lipomas. The average

ACC NO. 66

age of the patients was 43 years, with extremes of 34 and 62. The tumors were present for as little as three months and as long as three years. Five were in the upper inner quadrant of the breast and 2 in the upper outer quadrant. Six were described as soft, superficial and apparently lying on top of the mammary tissue. They were unattached, freely movable and, with 2 exceptions, nontender. One was described as firm, tender and attached to the skin; it had followed a previous injury to the breast in that area. The average size was 3 to 4 cm. There was one man in this group. If gynecomastia is excluded, lipomas are the most commonly observed benign tumors in the male breast. Local excision was performed in each case. In one the tumor was recurrent, having been excised elsewhere three years previously.

Three patients had spontaneous abscesses; 1 was a man with a tense painful mass, of two weeks' duration, in the upper inner quadrant of the breast. Incision and drainage was all that was necessary. It resembled an abscess elsewhere in the body, and, although the etiologic basis was obscure, it may have arisen from the glands of the skin. The other 2 abscesses probably developed on the basis of chronic cystic mastitis. One patient never became pregnant, and in the other the abscess developed before pregnancy, so that pregnancy and lactation could be excluded in both cases. After spontaneous rupture, draining sinuses persisted for six months and two years, respectively. Both abscesses were painful and would discharge intermittently for a few days, then disappear, only to recur again in another week or two. There was a small induration beneath each. Complete local excision effected a cure in both cases.

There was 1 patient with fat necrosis. Recognition of this peculiar condition is important because it so frequently mimics carcinoma. The patient was 24 years of age and was accidentally struck in the breast four months previously by a companion's elbow. One week later she noticed a lump in the lower inner quadrant of the left breast. It was not tender and did not increase in size but seemed to become firmer. Examination disclosed a solid tumor, not freely movable and with a suggestion of slight induration. It was unattached to the overlying skin. Local excision and examination revealed fat necrosis with microscopic evidence of abscess formation.

Accessory mammary tissue in the extreme tail of the breast, near the axilla, may present another confusing picture. One patient had bilateral masses in the tail of each breast. The patient was 51 years of age and for one year had noticed slight soreness and tenderness in the extreme tail of each breast, where there were soft, bulky, slightly thickened, poorly outlined masses near the axilla, more pronounced on the left side (fig. 4). Local excision on the left was performed. Microscopic examination revealed normal aberrant breast tissue.

SUMMARY AND CONCLUSION

1. Great headway in public health education seems to have been made in patients with tumors of the breast. This increases the responsibility of the members of the medical profession toward making an accurate diagnosis of all mammary conditions, benign and malignant.

2. The relationship between chronic cystic mastitis, the most commonly observed condition in 100 consecutive cases of benign diseases of the breast, and cancer is still confused. The former is a disease which involves all of the mammary tissue and is characterized by many histologic features. Local excision, the treatment of choice, is not curative but is the only certain way to rule out the presence of cancer.

3. Adenofibromas occur predominantly during the child-bearing period. Accurate diagnosis in these patients is more readily obtained than with other tumors of the breast. Early local excision is important, due to the rapid increase in size during periods of estrogen stimulation and the possibility of malignant transformation.

4. Bleeding from the nipple is a cardinal symptom of papillomas of the duct. Accurate localization is necessary in treating these tumors. When this has been accomplished and the benign nature of the tumor has been verified, local excision is the only treatment necessary.

5. A somewhat heterogeneous group of tumors was found in the remainder of the 100 patients with benign conditions of the breast. These included lipomas, abscesses, fat necrosis and aberrant breast tissue. All of them were noncancerous but are of diagnostic importance and cause much worry and anxiety to the patient.

# OPERATIVE VS. NONOPERATIVE PROCEDURES FOR UTERINE FIBROIDS

ROBERT T. FRANK, M.D.
New York

Every week day for almost fifty years I have been seeing, examining and advising women who are sick or believe themselves to be sick. A large number are fear stricken and panicky. Some hide it because of pride, upbringing and convention; others show naked fear unashamed. Their fear is of invalidism, pain, tumor, cancer and death. They may have watched a sick member of their family fade away, listened to gruesome gossip from a neighbor and, to culminate it all, have been told tactlessly by their physician that they have a tumor in the breast, womb or ovary which requires immediate operation. The impression made by this or analogous combinations of events causes a fixation which may resist all attempts to convince them that the condition is harmless, nonmalignant, and does not require operation. Today, the widely publicized cancer campaigns, the insistence of the public itself on the routine making of vaginal spreads for cancer, the overzealous, inexperienced routineers who man many clinics and who fail to recognize the wide variations which nature still considers normal, who heedlessly and needlessly frighten patients, are rapidly increasing individual panic into a national stampede. Unchecked this movement will leave in its wake a wide swath of hopelessly neurotic persons, of disabled and unnecessarily mutilated women.

By far the most numerous "tumor" encountered in women is the fibroid, or more properly called fibromyoma of the uterus, a muscle growth, almost certainly produced by some excess or imbalance in the secretion of the female sex hormones.[1] In many ways fibroids of the uterus resemble adenoma of the prostate in the male. One striking difference, however, is that while cancer in adenoma of the prostate is frequent, malignancy in fibroids is exceptional.

The health, happiness and future morale of many a patient will rest on the tact, insight and kindliness with which the attending physician, most often the general practitioner, the "family physician," enlightens her about the presence of a fibroid of the uterus. If his knowledge and experience do not qualify him to give a decisive verdict, he should at least offer reassurance and request a qualified opinion from a specialist. Unless this precaution is observed, it makes future treatment difficult or impossible, unless it coincides with the first opinion voiced, which may well have been faulty. Selection of therapy, if such be needed, should be done only after consultation and discussion with a competent gynecologist.

---

[1] Lipschutz, A.: Experimental Fibroids and the Antifibromatogenic Action of Steroid Hormones, J. A. M. A. **120:** 171 (Sept. 19) 1942.

A number of problems arise in each case, which must influence and determine the method of treatment to be pursued. One patient, whose pelvis is blocked with fibroids, wants children. Another, whose uterus contains two or three minute fundal growths, has been terrified without valid basis and told she must never become pregnant. A third is flooding alarmingly. In not a few instances, I have found that patients referred for treatment of fibroids have no fibroids, a retroflexed uterus appearing enlarged to the uninitiate, or a subinvoluted uterus is diagnosed as fibroidal, or ovarian growths or intraligamentous exudates are mistaken for myomas.

As I mentioned at the outset, I have been seeing, observing and treating fibroids for nearly half a century. At the beginning of my career, in the early 1900's, supravaginal hysterectomy was attended with such a considerable mortality rate (peritonitis, intestinal paresis, postoperative pneumonia, embolism) that operation was performed as a last resort.[2] Fifteen years later, roentgen therapy was hailed as a major boon, a substitute for operation, and was used too indiscriminately until its limitations were recognized.[3] Myomectomy presented undue hazards and was confined to the hands of a few. Today advancement in anesthesia, the advent of blood transfusion, preoperative preparation and postoperative care, the antibiotics, the Miller-Abbott tube, early ambulation and anticoagulant therapy have reduced both the mortality rate and morbidity to a minimum. In consequence, both myomectomy and supravaginal, as well as total, hysterectomy, are resorted to frequently, often indiscriminately and sometimes unnecessarily.[4]

TABLE 1.—*Incidence of Symptoms*

| Symptoms | No. of Cases |
|---|---|
| Excessive bleeding | 309 |
| Prolonged bleeding | 194 |
| Urinary symptoms | 121 |
| Pain | 190 |
| Enlarged abdomen | 46 |
| No symptoms | 56 |

In order that the problem be presented fairly, as well as on a factual basis, my office staff took a large random sample from my private patient files. Three thousand case histories as they appeared alphabetically have been examined; every case in which fibroids were found has been analyzed and utilized in the tables which follow. These unselected cases date between 1925 and the time of reporting. What do they teach us?

## MATERIAL

The 916 fibroid bearers (30.5 per cent of the 3,000 gynecologic patients) exceed the number of persons with fibroids in the general population because they represent a group presenting themselves for gynecologic examination. Seven hundred and thirty-one were referred by physicians (80 per cent), and, of these, 331 were referred with the diagnosis of "fibroids" (45.3 per cent). However, it is known that fibroids occur in 4 to 11 per cent of women according to the observations in large groups of women.[5] How many symptomless tumors of small and moderate size never are discovered is a matter of pure conjecture, but, even in a group in which the diagnosis had been made, more than 6 per cent were found symptomless and 25 per cent complained of noncharacteristic troubles, not ascribable to the tumors, such as backache and dysuria (frequency, burning, spasm), dysmenorrhea and dyspareunia, symptoms noted in a wide variety of conditions.

## OBSERVATIONS

*Symptoms.*—The most frequent and characteristic complaint in fibroid bearers was excessive bleeding (309); next came prolonged bleeding or spotting (194). Disturbance of urination (121) and pain (190) of all varieties and locations, usually lower abdominal, backache, right iliac or groin, were in no way characteristic. Rarely was the pain situated over the tumor except in inflammation, torsion of pedunculated growths or in aseptic necrosis (usually during pregnancy). Abdominal increase was noted in less than 5 per cent. In about 6 per cent no complaints whatever existed. Concomitant symptoms, such as dizziness, anemia, high or low blood pressure, digestive disturbances and psychosomatic manifestations of infinite variety, as well as anxieties ascribable to the current "cancerphobia," serve to present a confused picture. Pressure symptoms were startlingly few. Only twice was rectal pressure complained of. Even tumors which are impacted and fill the pelvis or occupy a major portion of the abdominal cavity only exceptionally produce pressure symptoms such as severe bladder disturbance (1 case of ischuria paradoxa) or grave obstipation. Minor dilatations of the ureter probably are overlooked unless pyelograms are taken.

Because of their gradual development and somewhat vague symptom complex, most fibroids are discovered by accident unless bleeding draws attention to the uterus. However, now and then an emergency dramatically brings it into the foreground.

*Emergency Conditions.*—Yet in the 916 patients, only five surgical emergencies arose and of these only two were directly ascribable to the fibroids. The others were: one extrauterine pregnancy, a twisted ovarian cyst and peritonitis due to pneumococci.

CASE 1.—Mrs. A. T., age 38, was rushed to a hospital because of profuse bleeding. She was found in mild shock with 37 per cent hemoglobin. Vaginal examination disclosed a billiard-ball-sized fibroid with a thick pedicle extruding from the cervix. Transcervical enucleation was done and transfusion given. Sixteen years later, curettage was done with radium insertion for fibroids and menorrhagia.

[4] Miller, N. F.: Hysterectomy: Therapeutic Necessity or Surgical Racket? Am. J. Obst. & Gynec. **51:** 804, 1946. Similarly critical are Bieren, R. E., and Hundley, J. M.: Indications for the Removal of a Normal Uterus, Am. J. Obst. & Gynec. **54:** 321, 1947. No indications in 14 per cent and doubtful indications in 65.6 per cent.

[5] Crossen, H. S., and Crossen, R. J.: Operative Gynecology, ed. 6, St. Louis, C. V. Mosby Company, 1948. The authors, without quoting statistics or source, stated that "uterine fibroids . . . found in about 40 per cent of women aged forty." This seems an unduly high figure.

CASE 2.—Mrs. E. L., aged 41, was seen in consultation because of profuse bleeding five days after menstruation. The preoperative diagnosis was ovarian cyst with twisted pedicle, incarcerated fibroid uterus and possible ectopic pregnancy.

Operation within twelve hours showed a gangrenous pedunculated fibroid three times the size of the uterine fundus. Gangrene was due to torsion of the pedicle. After supravaginal hysterectomy, the patient had an uneventful recovery.

In my entire experience I can recall only 2 other cases of real emergency. The patients are not included in the 916 analyzed. I am describing them here in order to emphasize the rarity of emergencies requiring immediate operations.

CASE 3.—Miss R. W., age 35, was referred because of "tumor," the size of a 6 month fetus, and fibroids. The cervix was red and granular—a suspect erosion. The patient was admitted to the hospital, a biopsy of the suspect area was made. Severe bleeding not controllable by suture or cautery necessitated the patient's immediate transfer to the operating room, where a Wertheim operation was performed. The diagnosis was squamous cell carcinoma of the cervix and fibroid uterus. Postoperatively high voltage roentgen therapy was given. The patient was well eight years later.

CASE 4.—Mrs. H. S., age 46, was seen in consultation with a history of pelvic inflammation six years previously. One day after the onset of the menses, the patient had exquisite pain, temperature of 103 F., pulse rate 110 and diffuse abdominal tenderness. A large fibroid uterus reaching to the umbilicus was felt. The preoperative diagnosis was an acute abdominal condition due to rupture of a tubo-ovarian abscess or some change in the fibroids. Immediate operation revealed free pus in the abdomen, right ruptured pyosalpinx with appendix adherent and large fibroids. Supravaginal hysterectomy with complete peritonealization, bilateral salpingo-oophorectomy and appendectomy were performed. The patient had a smooth convalescence.

Aseptic necrosis manifests itself by excrutiating localized pain. I now try to tide over aseptic necrosis during pregnancy with hibernation and penicillin. This usually is feasible.

Often doctors are more frightened by hemorrhage than are the patients. It is true that being called to a home at 2 a. m. and finding a jittery husband, a terrified woman hunched in bed and writhing with cramps, with the bed clothes soaked and clots between the thighs, can be disturbing and misleading. First the diagnosis—an abortion in process or menorrhagia or metrorrhagia—must be made. The mere presence of fibroids is not decisive, as they may be present in either condition. Reassurance, a clean up of the field and aseptic local examination is indicated. Administration of an ergot preparation (a 0.2 mg. tablet of ergonovine maleate, or an ampule of ergot by hypodermic for quicker action) will show how controllable the bleeding is and give breathing time. Every physician should have the means of taking a hemoglobin reading at hand; a Tallquist paper scale is adequate. If the reading is above 60 per cent, no keen anxiety need be felt.

*Examination.*—Far oftener the physician is consulted at his office with the history of menorrhagia and metrorrhagia of varying duration. These symptoms, or urinary complaints, backache and the like, should induce him to make a pelvic examination, examine the catheterized specimen of urine and expose the cervix for visual inspection.

It would be far better if at the first visit of every new patient—with the exception of the few who are too terrified, uncooperative or reluctant, a small group readily recognized by the more experienced practitioner—the physical examination routinely included a vaginal, or in the unmarried or virginal, a rectal examination. Earlier recognition of latent conditions would be the rule. Of course, I have to take for granted that the physician's training and knowledge is adequate and therefore will make such an examination meaningful. If a pelvic tumor is thus discovered this may signify a great variety of possibilities, including uterine fibroids, fibroids and pregnancy, ovarian tumors, inflammatory exudates and rectosigmoidal neoplasms. The diagnosis is not always easy or possible.

It is needful, when some pelvic abnormality is discovered, to exercise tact and care. What the physician now says, I again repeat, may indelibly influence the future health, happiness, morale and even the fate of the patient. An incautious "You have large fibroids (they may be walnut sized [sic]), which must come out at once" may produce panic and an ineradicable conviction that operation is essential. For some patients no reassurance from no matter how authoritative a source will obliterate such an unwarranted snap verdict, and in due time she will find an operator willing to mutilate her without valid indications.

If, on the other hand, the family physician informs the patient that there appears to be something not quite right in the pelvis which he would like a specialist to feel, this may cause some temporary alarm or disquiet but not a fixed and firm conviction with ineffaceable localization as previously described.

In the present series, 80 per cent of patients with fibroids were referred by physicians, and of these the disease in 331, or 45.3 per cent, was diagnosed correctly by the referent as fibroids. However, I had to disagree as to the treatment to be pursued in more than 50 per cent of these—more often on the side of watchful waiting than on that of "immediate operation."

A consultant must employ tact and circumspection in enlightening a patient. He should form his own opinion unbiased by previous verdicts, but, in stating it to the patient, he should not minimize the opinion of the family physician if this differs from his own. One can tone down unnecessary urgency, can remove or allay the fear of cancer and emphasize the safety of further observation in those who have been told that immediate operation was necessary.

Of 916 cases, I had the opportunity of observing only 340 (37.1 per cent) for one to twenty-three years (187 up to two years, 50 for two to four years and 103 for four years or more). The majority of patients, 576 (62.9 per cent) were transient, seen only once or twice for opinion as to the therapy to be pursued. The further course of many was reported by their physicians, but, unless the patient was again seen, such reports have not been incorporated here.

Even if the practitioner for one reason or another is unable to make a reliable diagnosis of pelvic conditions, and consequently is even less in a position independently to decide on subsequent treatment, he should at least be able to judge whether the recommendation as to therapy which he receives from the specialist appears sound and shows good judgment.

Some of the many factors on which the decision as to further observation, palliative interventions or radical operation should be based are analyzed.

*Social Status.*—The uterus in a woman of 46 years who is the mother of 3 children may be of less importance than is the womb of a young woman of 24 engaged to be married. Yet this does not excuse the recent dictum of a well known colleague who told a 40 year old woman suffering from slight menometrorrhagia of short duration (cytologic spreads normal, small fibroids, normal cervix), "Your uterus is of no further use to you; it should come out." I have encountered this same point of view again and again.

Table 2.—*Status with Respect to Marriage and Children*

| Status | | No. of Cases |
|---|---|---|
| Married | | 819 |
| With children | 534 (65.2%) | |
| Childless; abortions | 76 ( 9.3%) | |
| No pregnancies | 209 (25.4%) | |
| Single | | 97 |
| Total | | 916* |

* Thirty-three were seen during pregnancy and 38 in menopause.

In my series, 819 women were married; 534 (65.2 per cent) had borne children; 76 (9.3 per cent) had had miscarriages only; 209 (25.4 per cent) never conceived. This conforms with the accepted view that fibroids *per se* do not reduce fertility. Thirty-three were seen during pregnancy. Of these, in only 5 was interruption advised and performed for paramount reasons. The main indication is rapid growth of the myomas. When the total tumor at three months of gestation reaches seven months' size, it is unwise to procrastinate further. Laparotomy, hysterotomy with delivery of the fetus and, if technically feasible, myomectomy are indicated. In a few, myomectomy with continuation of pregnancy was undertaken (pedunculated or mainly subperitoneal growths—of these nearly 50 per cent carried to term). Thirty-eight patients were in or were entering the menopause.

*Age.*—Young Women: It is obvious that the age of a patient plays a considerable role in deciding on procedure. In young women desiring children, small fibroids, especially if subperitoneal and fundal, rarely prove of clinical importance during pregnancy. I advise that they try to become pregnant with little delay before the fibroids have had a chance to enlarge further. Especially careful watching up to the fourth month is essential. If by that time the entire uterine mass is no larger than a 6 to 6½ month fetus, a normal course may be anticipated. I have rarely regretted such decision. On the other hand, if by the second month of gestation, the fibroid mass has attained the size of a 5 month old fetus or is cervical, or there is a history of repeated spontaneous abortion, I advise myomectomy during pregnancy, because if these conditions are unrelieved patients do not carry to term.

Table 3.—*Age Incidence*

| Age Group, Yr. | No. of Cases |
|---|---|
| 20-30 | 37 |
| 31-35 | 86 |
| 36-40 | 97 |
| 41-45 | 145 |
| 46-50 | 102 |
| 51-55 | 26 |
| 56-75 | 7 |

A substantial number of young women harbor fibroids. These are usually discovered in the periodic health examination or at cancer clinics. Many are small, multiple and subperitoneal or intramural, enlarging the uterus not at all or only to the size of an 8 week old embryo (531 cases). The symptoms vary from none through menorrhagia and metrorrhagia (58 per cent). Small tumors should be watched; larger growths (5 to 7 month fetal size, 90 in number) require myomectomy or, if this is not possible, hysterectomy. Of the 31 patients who underwent myomectomy in this series, nearly 50 per cent had children after operation. No final and binding promise to perform myomectomy should ever be given, because local, unpredictable conditions may force the operator to perform hysterectomy.

Older Women: The age group 40 to 50 years showed more fibroid bearers than the 20 to 40 year group (247:220). As a group they had been fertile (only 25.4 per cent never pregnant). Besides the discovery of a "tumor," irregular and/or excessive menstruation was the major symptom. Each case demanded individual consideration.

First the general health and status of the patient were ascertained. The most frequent handicaps were cardiac, with coronary antecedent; next in frequency were renal and pulmonary complications, especially bronchiectases and chronic bronchitis; varicose veins (history of phlebitis); hypertension, and obesity. In my preliminary examination, the short, fat, breathless woman with hypertension and varicose veins is labeled "poor risk," and the indications for intervention must be overwhelming before I advise operation. These are the patients on whom roentgen rays and radium are most often properly used—32 in this series.

Table 4.—*Size of Fibroids When First Observed*

| Size* | No. of Cases |
|---|---|
| Unenlarged but small fibroids palpable | 43 |
| Minute, 8 weeks | 488 |
| 9-12 weeks | 137 |
| 3-4 months | 148 |
| 5-6 months | 80 |
| 7 months or more | 10 |
| Not stated | 10 |

*The size is expressed as analogous to that of a pregnant uterus.

Many women in this age group require operation because of large growths, severe and prolonged bleeding and consequent anemia, intermenstrual spotting and abdominal pain. Some had been observed for years with small tumors with few symptoms; eventually, however, growth and bleeding increased, necessitating intervention.

*Menopause.*—Thirty-eight women had reached or were entering the menopause when first seen. Their bleeding most often was due to injudicious or too early use of estrogens. Preliminarily the hormone therapy was stopped. Formerly curettage was performed routinely. Today the cervical and vaginal secretions are examined cytologically (Papanicolaou spread for atypical cells—requiring special knowledge and experience, as well as unlimited time to read these slides) and the patient closely watched. In this series not one case of ovarian neoplasm producing postmenopausal bleeding was encountered, but this possibility must be kept in mind. A number underwent curettage with or without radium insertion. Only 2 cases of malignant growths with fibroids were noted—in one, a corpus carcinoma, and in the other, a sarcoma in a fibroid. This is in sharp contrast with

20 cases of carcinomas of the corpus uteri found among the 3,000 histories analyzed, in which the differential diagnosis lay not between fibroids and carcinoma but between carcinoma and functional bleeding. This was ascribable to the fact that the uterus in these patients was either unenlarged or in postmenopausal patients even smaller than normal.

In the sole instance in which a fibroid increased in size after the supposed onset of the menopause, supravaginal hysterectomy was performed but no malignant growth found.

Occasionally a fibroid uterus the size of a uterus at three and a half to four months' pregnancy, lying in sharp anteflexion, after onset of the climax, shrinks somewhat and, though previously symptomless, now rests directly on the bladder and causes undue urinary frequency. This may necessitate removal.

The majority of fibroids which are less than the size of a 3 month embryo gradually shrink after the menopause and within five years are no longer palpable in the fully involuted senile organ. Today, however, this desirable involutionary process too often is delayed or indefinitely postponed by early, excessive and injudicious estrogenic therapy.[6]

Occasionally a stony hard pelvic tumor is encountered in an old woman who is examined because of some acute attack of abdominal pain. Roentgenograms show calcification. These are old calcified fibroids which somehow have escaped the scalpel of the zealous operator. They do not produce the abdominal symptoms complained of. The oldest patient (not included in this series) was a woman of 80, in whom at autopsy such a calcified fibroid was found; death was due to obstruction from an overlooked carcinoma of the splenic flexure.

TABLE 5.—*Variation in Size of Fibroids During Observation*

| Number of Years of Observation | Number of Cases | | Percentage |
|---|---|---|---|
| | Increased Size | Size Not Increased | |
| Up to 2 | 86 | .. | 46 |
| | | 101 | 54 |
| 2-4 | 28 | .. | 56 |
| | | 22 | 44 |
| 4-20 | 38 | .. | 36.9 |
| | | 65 | 63.1 |

*Cervix.*—A factor of importance in planning adequate treatment is the condition of the cervix.

In this series of 916 patients, the cervix was described as normal in 661. The commonest error is due to one's stretching the cervix of a parous woman when viewing it through a bivalve speculum. This opens the os widely, exposing the bright red cervical lining. This normally red area is then diagnosed as an erosion, an eversion or "a suspect cervix." If the speculum is partly closed, the cervical lips fall into apposition, as they normally lie, the canal lining is hidden and protected; if there is no cervical discharge, I regard such a cervix as normal.

Cervical lesions which may require treatment are nabothian follicles (cautery puncture), polypi (avulsion), erosions (silver nitrate 10 to 20 per cent, linear cautery) and endocervicitis (daily injection on three successive days of 300,000 units of crystalline penicillin). In virgins, unless the indications are special, I rarely visualize the cervix. When necessary, it can be viewed without discomfort to the patient, through a long no. 14 endoscope. When indicated, spreads or cultures for gonococci, biopsies of suspect erosions and cytologic smears are made and studied.

TABLE 6.—*Condition of Cervix*

| Condition | | No. of Cases |
|---|---|---|
| Normal | | 661 |
| Symptomless lacerations | | 49 |
| Erosions | | 45 |
| Polyps | | 42 |
| Nabothian follicles | | 24 |
| Endocervicitis | | 5 |
| Single; not visualized | | 80 |
| Miscellaneous | | 10 |
| Amputated | 5 | |
| Leukoplakia | 2 | |
| Angeiomas | 2 | |
| Vaginal septum | 1 | |

*Previous Operations.*—The treatment of patients, in some instances, must be modified because of previous operations. I habitually shy away from the proud exhibitor of three or more abdominal scars and regard with suspicion operations performed for "cystic" ovaries, with additional appendectomy and ligament shortening. I have seen a number of appendectomies patently performed for dysmenorrhea and "mittelschmerz." In my series of 916 patients, 310 (33.8 per cent) had undergone one or more operations. Only the major one is recorded for each patient. The majority were fully justified, and a gratifying number of patients had been relieved of their disabilities.

TABLE 7.—*Number of Cases with Operation Previously Undergone*

| Type | No. of Cases |
|---|---|
| Appendectomy | 107 |
| Dilatation and curettage | 39 |
| Breast exploration | 31 |
| Myomectomy | 19 |
| Ovarian operation | 22 |
| Tubal | 15 |
| Uterine ligament operation | 16 |
| Gallbladder operation | 14 |
| Thyroid operation | 11 |
| Vaginal plastic | 9 |
| Cesarian operation | 6 |
| Hernioplasty | 4 |
| Miscellaneous | 7 |
| Total | 310 (33.8%) |

## TREATMENT

The treatment here suggested is based on experience and is correlated with the material so far presented. This does not imply either that my judgment was faultless, or that it was not necessary in many instances to modify or change the method of treatment of patients under observation, which in some instances extended over periods of ten to twenty years.

However, it may be noted (table 4) that in 43 cases the fibroids were so small that they did not enlarge the uterus. This usually signifies cherry-pit-sized to *cherry-sized fibroids subperitoneally located and therefore* readily palpable. In 488 cases the fibroids did not enlarge the uterus above the size of a uterus of eight weeks' pregnancy. In other words, in this large group close to 58 per cent of fibroids were of such small size that from the dimensional point of view they were negligible. Such fibroids may have been *accidental discoveries*, if symptomless, or have produced menorrhagia and/or metrorrhagia of slight to major degree, or they may have been noted in patients suffering from functional bleeding. I shall return to this important point of differential diagnosis.

---

[6] Estrogens given for the relief of the neurovascular symptoms of the menopause should be prescribed in such a fashion as to eventually permit of their complete withdrawal. The present tendency to prescribe estrogens while a patient still menstruates, either regularly or irregularly, is to be decried. This premature "therapy" produces a train of symptoms which I miscall "estrogenitis"—irregular and often profuse bleeding, a thick, pasty discharge (squamous epithelial cells) and painful breasts. After the menopause has set in, I prescribe the lowest effective dose, usually a 0.5 or 1 mg. tablet of diethylstilbestrol to be taken before retiring. It is taken for twenty-eight days and then stopped until the flushes again become severe. The patient is instructed to prolong the time between each twenty-eight day "course" more and more, so that eventually she will require no more drug.

*Malignancy.*—There is no excuse for one's regarding fibroids as potentially malignant either because an ever decreasing number are found to be sarcomatous (the decrease being due to the more rigid criteria observed by the pathologist—formerly up to 10 per cent and now far below 1 per cent) or as favoring carcinoma formation.[7] In the present series, only one sarcomatous fibroid and one adenocarcinoma of the corpus occurred (0.2 per cent). The sarcoma was noted within a fibroid. The patient remained well after supravaginal hysterectomy. The other patient was operated on by me at the age of 36 years, a large left dermoid was removed and a billiard-ball-sized fibroid was excised from the fundus uteri. The patient then was lost sight of for five and a half years, when she returned to complain of intermenstrual staining. The uterus was the size of one at three months' pregnancy. At operation the uterus was found immobile in a rigid parametrium. Only supravaginal hysterectomy could be performed. The diagnosis was infiltrating adenocarcinoma of the corpus and multiple fibroids. Postoperatively a radium pack was used. The patient lived for two and a half years, dying from general abdominal carcinosis.

*In the majority of instances*, the patients that I see have been told that they required operation, often radical intervention, because of the imminent danger of cancer. The majority of those not referred by physicians usually come of their own accord because they had been told by another physician that they must submit to operation immediately.

*Medical Measures.*—Years ago I performed dilatation and curettage more frequently for excessive bleeding than I do now. At the time it was the only way known to explore the uterine cavity in order to discover submucous fibroids and what then was also considered causative of bleeding, namely, "polypoid endometrium." Today the latter is regarded as a consequence of excessive estrogenic stimulation. If ergot therapy did not control the bleeding, the curet was resorted to. Today a hysterogram, with a watery, not an oily, contrast medium, in skilful hands, is a harmless office procedure which reveals the gross abnormalities in the cavum. In order to evaluate how much of the bleeding is functional (recognizing, of course, that fibroidal growth itself is almost certainly the result of excessive or abnormal estrogenic stimuli) I now employ *with increasing confidence a modification* of the method introduced by Karnaky. A bleeding patient is given 10 mg. of diethylstilbestrol in tablet form while still in the office, and 5 mg. tablets are *given nightly* for twenty to twenty-five days. The reduction in gonadotropic secretion produced by the large dosage of estrogen (25,000 international units per milligram) should by that time reduce the excessive bleeding. The cessation or reduction in bleeding gives the attendant a breathing spell, permitting further observation and evaluation of the situation. Full and continued control of menorrhagia and metrorrhagia obtained by this therapy signifies a predominantly functional element and justifies one's further observation and occasional repetition of the "cyclical diethylstilbestrol course," keeping in mind that this powerful estrogen might, if too long continued, stimulate additional growth of the fibroids, although I have never as yet observed this effect.

*Curettage.*—Failure of medical measures (ergot, diethylstilbesterol) and unchecked bleeding with increasing anemia (hemoglobin 70 per cent or lower) justifies dilatation and curettage with general anesthesia —rarely with local paracervical anesthesia in the presence of severe constitutional disease. Particularly in women approaching the menopause this palliative operation proves effective. I performed it sixty-five times (28.5 per cent of operations). In this series *it was combined only once with radium insertion in* order to bring on the permanent menopause. Needless to say, the curettings were examined microscopically, but the results were unrevealing and uninformative except to exclude carcinoma. My insistence on this examination, quite understandably, is based on the necessity of one's never overlooking intracorporeal or high cervical malignant growths. The curet also discloses submucous fibroids projecting into the uterine cavity.

Only rarely have I removed a small uterus for intractable bleeding after dilatation and curettage has failed and when the patient is below 45 years of age. In the older group, sterilization by intrauterine administration of radium or roentgen rays is justified. Below this age, hysterectomy with retention of the ovaries is a preferable and far less radical measure. Occasionally poor physical condition makes radiation therapy the lesser danger in the younger patient.

*Size.*—In a more detailed analysis of 464 patients divided into three groups according to the size of the uterus, in the group with no enlargement up to the increase in size of eight weeks' pregnancy, it was *found justified to watch* 54.2 per cent of the patients; when the uterus reached the size of two to four months' pregnancy only 39.7 per cent were watched; of those larger than this only 18.4 per cent were deemed watchable. It follows that a reverse trend was noted in the operations performed or recommended, namely 45.8 per cent, 60.3 per cent and 81.6 per cent, respectively. In group A dilatation and curettage equaled 23.5 per cent; in group B, 16 per cent, and group C, 4.6 per cent. Hysterectomy, on the other hand, was indicated in group A in 7 per cent of the cases; in B, 37 per cent, and in C, 72 per cent. *In large tumors, the size of four months' pregnancy and larger*, operative intervention is indicated with increasing frequency (table 9).

If the tumor when first observed is the size of a 2 to 4 month fetus (table 4) (285 cases, or 31 per cent), it still is within dimensions which may be observed safely under certain conditions (35.1 per cent). Many factors may demand consideration, such as active and severe symptoms (bleeding, pain, dysuria), desire for children or existing pregnancy. When the growths are small, myomectomy rarely is indicated, unless performed in the course of other operations (ectopic [2], ovarian cysts, vaginal plastic, transcervical avulsions of submucous growths).

---

[7] Frank, R. T.: Gynecological and Obstetrical Pathology, ed. 2, New York, D. Appleton and Company, 1931, p. 230. In large series of cases, cancer seemed purely coincidental with fibroids (Kelly and Cullen, 1,400 cases, 1.7 per cent; Noble, 1,118 cases, 2.4 per cent; in my own series, 400 cases, 0.5 per cent; McDonald, 700 cases, adenocarcinoma of corpus, 2.9 per cent and cervical carcinoma 0.8 per cent).

Of tumors larger than a 4 month fetus, a subgrouping into between 4 to 5 months, 5 months, 6 months and 7 months showed that in the 4 to 5 month group, 16 per cent were not operated on; in the 5 month group this figure dropped to 9 per cent, and in the next two groups it was deemed advisable to perform operation on all.

*Operation.*—Although the final decision as to the type of operation rests with the surgeon, the family physician, who knows the patient, her background, resistance, stability or lability and psychic makeup, should have some voice in deciding whether the operation should be conservative (dilatation and curettage, myomectomy) or radical (dilatation and curettage and radium therapy, supravaginal or complete hysterectomy, retention or removal of the ovaries). Unless there are special reasons, such as a morbid dread of the menopause or great psychic lability, I remove the ovaries routinely in women of 45 years or over, because in a small number these ovaries years later develop cysts or malignant changes, necessitating reoperation, sometimes too late to save the patient.

It is my custom, if the pelvis after hysterectomy is dry, the patient is in good condition and the appendix is readily accessible through the left paramedian incision, to perform a prophylactic appendectomy (30 per cent). However, in myomectomy, as some postoperative oozing is almost unavoidable, I rarely remove the appendix.

*Complete Versus Supravaginal Hysterectomy.*—If the cervix is normal and the indication for hysterectomy is clearcut and warranted, one must decide whether to perform a supravaginal hysterectomy or a complete hysterectomy. Today "the fashion," I use this term advisedly, as I have lived through many, often transient, trends, favors complete hysterectomy. I rarely remove the cervix in nonmalignant conditions. Of 358 hysterectomies in a series of about 10,000 patients, including the 3,000 here analyzed for fibroids, only 13 were complete; this included 8 vaginal hysterectomies. On the other hand, I have been consulted by a number of women for whom total hysterectomy had been performed by others, who complained of dyspareunia, dryness of the parts and (3 cases) complete eversion of the vagina. Moreover, I have been obliged to repair a not inconsiderable number of vesicovaginal fistulas which resulted from complete hysterectomy performed by various operators.

I have never observed a stump carcinoma in any of my patients for whom I had performed a supravaginal hysterectomy. This record must be due at least in part to the care which I observe in restoring the cervix to normalcy before operative intervention. It must also be ascribed in some degree to the fact that my patients predominantly are Jewish. It is well known that cervical carcinoma is infrequent in Jewish women.[8] On the other hand, in this same limited group of 3,000 patients, twenty carcinomas of the corpus uteri were encountered (0.66 per cent) in the absence of fibroids, and one sarcoma in a fibroid.

*Safety.*—Today, as mentioned in the introductory remarks, the safety of hysterectomy has been improved greatly. In 358 hysterectomies (unselected and in sequence), only 1 death occurred—the twenty-seventh in the series. Since then 331 have been performed without a fatality.

The sole death occurred on the eighteenth postoperative day, with anginal symptoms. As no autopsy was performed, it is impossible to exclude embolism with certainty, although the electrocardiogram was typical of coronary occlusion. There were no deaths in 95 consecutive myomectomies or in any of the curettages.

I have analyzed the material, with the object of determining, partly for my own satisfaction, whether the very conservative attitude with which I treat uterine fibroids is justified. The death rate in abdominal operations for fibroids (453) was 0.22 per cent, which is small. The operative mortality as published in the literature varies between 1 and 2.5 per cent.[9] Although the risk incurred by operation is not excessively great, this in no way justifies operation when not indicated. Too often small symptomless fibroids are removed either by myomectomy or by hysterectomy if the woman "no longer needs her uterus." The patients are frightened into consent by allusion to the possibility of cancer or the danger of excessive hemorrhage. I can make this criticism with assurance because of the many patients—including very poor risks—whom I have literally saved from operation and then observed for many years. Few of these have, because of new developments, required operation subsequently.

TABLE 8.—*Size of Uterus*

| | Number of Cases | | |
|---|---|---|---|
| Status | A * | B * | C * |
| Operation indicated........ | 137 (45.8%) | 70 (60.3%) | 40 (81.6%) |
| Watching advised.......... | 162 (54.2%) | 46 (39.7%) | 9 (18.4%) |

* In group A the uterus was the size of that in pregnancy up to eight weeks, in group B, two to four months and in group C, above four months.

TABLE 9.—*Operation*

| Size * | Number of Cases | Comment |
|---|---|---|
| 4 months | 31 | 14 operated on by me<br>12 operations advised<br>5 no operation (1 pregnant, 1 poor risk, 1 menopause)<br>2 myomectomies |
| 5 months | 34 | 16 operated on by me<br>15 operations advised<br>3 no operation (1 in menopause, 1 pregnant, 1 diabetes)<br>4 myomectomies |
| 6 months | 15 | 3 operated on by me<br>12 operations advised<br>4 myomectomies |
| 7 months | 3 | 3 operated on by me<br>0 myomectomies |

* Size is expressed as analogous to that of the uterus in pregnancy.

[9] Weir, W. C.: A Statistical Report of 1771 Cases of Hysterectomy, Am. J. Obst. & Gynec. **56**: 1151, 1948 (panhysterectomy in 71 per cent, vaginal hysterectomy in 11 per cent, supravaginal in 18 per cent; mortality rate, respectively, 1.13 per cent, 1.68 per cent and 0.93 per cent). Munnell, E. W.: Total Hysterectomy, Am. J. Obst. & Gynec. **54**: 31, 1947. (Of 1,798 hysterectomies at Bellevue Hospital, 1,583 were subtotal, mortality rate 1.76 per cent, and 215 were total, mortality rate 2.32 per cent.)

SUMMARY

1. Fibromyomas of the uterus, the most frequent tumors of the female genital tract, are functional growths dependent to a large degree on estrogenic stimulation.

2. In 3,000 unselected gynecologic patients, 916, or 30.5 per cent, had fibroids. This undoubtedly is a higher percentage than that of the female population in general.

3. The most frequent and characteristic symptoms of fibroids are excessive bleeding, prolonged bleeding or too frequent uterine bleeding (54.7 per cent). Pain occurred in 20 per cent; 6.2 per cent had no symptoms whatever.

4. Emergencies requiring immediate surgical intervention are most unusual, only 6 in 916 cases. In only 2 was the emergency due to the fibroids themselves (torsion of subperitoneal growth, extrusion through the cervix).

5. Pelvic examination should be performed routinely by the general practitioner; conversely, the gynecologist should likewise examine his patients completely to weed out poor risks.

6. When the general practitioner discovers uterine fibroids, he should be cautious and reserved in announcing the presence of a "tumor" to the patient, in order to avoid alarming and producing a severe and permanent psychic trauma. He may safely tell the patient that:

(*a*) Fibroids rarely require emergency treatment.

(*b*) They do not lead to cancer formation.

(*c*) More than 50 per cent may be watched and may never require operation.

(*d*) Small fibroids situated on the fundus rarely interfere with pregnancy and safe delivery.

(*e*) At the menopause small fibroids involute and disappear.

7. In the presence of any pelvic tumor, the question of differential diagnosis of fibroids, pregnancy, abortion, corpus, even cervical carcinoma and functional bleeding arises constantly. Pregnancy tests, vaginal and cervical cytologic smears, hysterograms, response to diethylstilbestrol and eventually dilatation and curettage are utilized in this differentiation.

8. The age of the patient, the parity, the wish for children, the variety and intensity of symptoms and the amount of disability all must be considered and weighed in deciding on treatment.

9. The "poor risk" patients—those with cardionephritic or pulmonary disease and obese persons—should not be subjected to abdominal operation. In them, dilatation and curettage and radium or roentgen therapy are indicated as palliative or curative measures.

10. Involution of fibroids near or at the menopause is delayed by premature administration of estrogens.

11. Fibroids up to the size of a 3 month fetus may be expected to shrink to clinically unimportant residua with the menopausal involution.

12. The condition of the cervix plays an important role in therapy. Nabothian follicle, erosion, polypi and endocervicitis require correction before operative measures are undertaken.

13. In this series, 33.8 per cent of patients had undergone one or more operations previously.

14. Fifty-eight per cent of the fibroids were negligible from the dimensional point of view—not above the size of an 8 week old fetus. Of these 54.2 per cent lent themselves to extended observation, the patients being seen twice yearly.

15. Medical measures include correction of cervical lesions, ergot therapy for excessive bleeding (not more than two days in one cycle to avoid ergotism) and cyclical prescription of diethylstilbestrol.

16. Palliative operations include curettage and myomectomy.

17. Radical intervention includes dilatation and curettage with radium insertion, roentgen rays given through multiple ports of entry in especially poor risks, and abdominal and vaginal hysterectomy.

18. To decide on the procedure indicated in the treatment of fibroids and pregnancy requires expert experience.

(a) A mass above the size of a 6 month old fetus seen in a patient in the second or third month of gestation will rarely allow gestation to proceed to term and usually necessitates myomectomy.

(b) Fibroids blocking the pelvis may require myomectomy early or cesarian operation and myomectomy at term.

(c) Aseptic necrosis, especially in pregnancy, in spite of pain and fever, usually subsides with conservative treatment.

19. Fibroids above the size of a 4 month old fetus necessitated operation in 90 per cent of the patients.

20. In my opinion, routine complete hysterectomy for fibroids is unjustified. It entails added risk and side injuries and leaves a dry and more shrunken vaginal canal.

21. The present tendency in the treatment of fibroids still is too radical. Operation is performed too often.

1035 Park Avenue.

# PERIPHERAL NERVE INJURIES FROM ADMINISTRATION OF PENICILLIN

## Report of Four Clinical Cases

THOMAS RAY BROADBENT, M.D.
GUY L. ODOM, M.D.
and
BARNES WOODHALL, M.D.
Durham, N. C.

Toxic effects of penicillin have been described in experimental animals and human beings affecting the meninges, nerve fibers and the cerebral cortex. Walker, Johnson and Kollros[1] demonstrated that penicillin injected into the cortex of monkeys or men induced convulsions. They also showed, by duplicating their results with pure crystalline penicillin, that these convulsions were not due to impurities that may be found in crude penicillin. Walker and Johnson[2] and later Walker, Johnson and Kollros[1] demonstrated convulsions as an indication of toxicity when penicillin was applied to the cerebral cortex of cats, dogs, monkeys and human beings. They observed electroencephalographic changes which paralleled these convulsive and subconvulsive states. Borkowski and Forster[3] stated the belief that these results might have been obtained from the intracortical injections, but later supported the work of Walker and his group by reproducing the

[3] Borkowski, W. J., and Forster, F. M.: Convulsant Effects of Penicillin on the Cerebral Cortex, J. Neuropath. & Exper. Neurol. **6**: 201, 1947.

convulsions and electroencephalographic changes by applying penicillin-soaked pledgets to the cerebral cortex of cats. Histologic changes in the cerebral cortex after the injection of penicillin have been noted by Walker and Johnson.[4] These effects following the use of penicillin intrathecally have been described by Sweet, Dumoff-Stanley, Dowling and Lepper[5]; Erickson, Masten and Suckle[6]; Siegal[7]; Bailey,[8] and others. Sweet and his co-workers[5] observed mild sensory changes as one variant and various degrees of motor paresis associated with hypotonic bladders, urinary retention and complete paraplegia as another form of clinical manifestation of toxicity. Erickson and his co-workers[6] concluded that a moderate toxic reaction to intrathecal penicillin therapy resulted in adhesive arachnoiditis and a severer response exhibited itself as transverse myelitis. Siegal,[7] Bailey[8] and others have also made this observation and have noted that such a response occurs about ten days after the injection. Walker and Johnson,[4] Erickson[6] and others have noted manifestations of radiculitis in animals and human beings; and Walker and Johnson[4] have demonstrated demyelinization and adhesive arachnoiditis in experimental animals.

In spite of the widespread parenteral use of penicillin in various vehicles and in various concentrations, there appears to be but one report suggesting a toxic effect on the peripheral nervous system. In 1946 Kolb and Gray[9] described "localized peripheral neuritis" in 7 patients who had received multiple intramuscular injections of penicillin for various infections. These patients characteristically noted changes ten to twenty-one days after their treatment and in some instances in the course of therapy. In each case the motor disability was greater than the sensory loss. In 2 of the 7 cases, muscular weakness persisted beyond the observation period of five months. The protocols of 4 of the 7 cases reported, cases 1, 2, 4 and 6, described the administration of the penicillin in the region of a nerve trunk subsequently affected by the neuritic process.

This report will describe the clinical course of 4 patients in whom there developed a peripheral nerve lesion immediately following the administration of penicillin into or about a peripheral nerve. This penicillin-induced lesion was characterized by the rapid onset of severe tingling pain of short duration, a pronounced and only slowly improving motor disability and a moderate inactivation of sensory axones.

## REPORT OF CASES

CASE 1.—C. S., a 6 year old white girl, received 1 cc. of penicillin in wax and oil, 100,000 to 300,000 units, in the course of treatment for an infection of the upper part of the respiratory tract given intramuscularly in the left buttock. She at once began to cry and complain of severe pain radiating from the point of injection down the posterior aspect of the thigh, the lateral aspect of the calf to the lateral half of the foot. Within fifteen minutes her attending physician noted the loss of all deep tendon reflexes and a paralysis of all of the muscles innervated by the sciatic nerve. The pain persisted ten days. Return of motor activity began after one month and had progressed steadily. No sensory changes or loss of sweating were described by the parents, although they had noted that the left extremity was colder than the right.

On examination in the outpatient clinic thirteen months after the injection, it was noted that the patient walked with a slapping gait characteristic of one with a sciatic nerve paralysis. The sciatic nerve was palpable but not tender. The gluteal musculature was normal. An estimated 25 per cent weakness of the biceps femoris existed, as well as a 60 per cent weakness in motor power of the gastrocnemius and soleus muscles as compared with the intact extremity. The intrinsic musculature of the foot was similarly affected. The extensor musculature of the foot and toes functioned against gravity but fatigued rapidly. There was no sensory loss; sweating was normal, and the skin temperature was equal to that of the unaffected extremity. Since the motor disability was improving, the patient was returned to the referring physician for continued physical therapy.

In the follow-up examination eighteen months after the injury, it was observed that the atrophy had almost entirely been replaced by normal musculature. Motor activity approached normal. The involved muscles did not fatigue so rapidly, and an estimated 30 to 50 per cent of her initial motor disability had returned to normal.

CASE 2.—H. A., a 43 year old white woman, was operated on in the Duke Hospital for a pelvic disorder. Postoperatively she was given aqueous penicillin every three hours, in 30,000 unit doses. On the third day after operation an injection was given rather far posterolaterally in the left arm in the region of the triceps muscle. She immediately experienced pain radiating down the posteromedian aspect of the upper arm and the medial aspect of the forearm into the fourth and fifth fingers. The tingling paresthesia was followed by a feeling of pressure in the fingers described as "as if my fingers were going to fall off." Sensory loss was complete over the ulnar dermatome but disappeared rapidly and completely within the next three hours to be supplanted by tenderness over the ulnar nerve distribution, which was still present at the time of neurosurgical consultation eight months after the injection. The patient had noted decided weakness on hand grasp, but this progressively improved.

At the time of examination pressure over the ulnar nerve elicited a tingling paresthesia spreading distally. The nerve segment was tender when palpated at the epicondylar groove. There was mild atrophy of the ulnar aspect of the forearm, the first interosseous space and the hypothenar eminence. There was slight hyperextension of the proximal phalanx and flexion of the distal phalanx of the fifth finger, indicative of an ulnar nerve injury. There was an estimated 10 per cent loss of motor power in all muscles innervated by the left ulnar nerve. There was no sensory loss, and skin temperature and sweating were comparable to the unaffected extremity.

On examination fifteen months after the injury, palpation over the course of the ulnar nerve at and above the elbow still caused pain and tingling paresthesia. Motor power had improved, but the patient thought that 50 per cent of the original disability still was present. There was no detectable atrophy, but weakness of all the muscles innervated by the ulnar nerve was definite and objectively only moderately improved.

CASE 3.—R. D., a 34 year old white man, received aqueous penicillin as treatment for a superficial leg infection. During the process of administration of one of his treatments, 100,000 units, in the midportion of the upper arm, he experienced severe aching pain radiating from the site of injection posteriorly to the lateral aspect of the elbow. He was nauseated and felt as if he would faint. As the penicillin was injected the pain increased, and over the next three to four seconds a sense of numbness progressed down the radial extensor surface of the forearm to the base of the thumb and second finger. At this time a wrist drop was noted and extension of the digits was impossible. For two weeks tingling persisted over the distribution of the superficial radial nerve, and for several more weeks intense sensitiveness over the course of this nerve was noted.

[9] Kolb, L. C., and Gray, S. J.: Peripheral Neuritis as Complication of Penicillin Therapy, J. A. M. A. **132**: 323 (Oct. 12) 1946.

At the time of examination eight months later, extension of the fingers, wrist and elbow was lacking. Abduction of the thumb was lost, and all muscles innervated by the radial nerve were atrophic. Faradic current stimulation produced no response in any of the muscles supplied by the radial nerve. The triceps and radial tendon reflexes were absent on the left, and evaluation of reflexes on the right was 2 plus. There was hypalgesia over the usual sensory domain of the radial nerve. The left radial nerve was explored with local anesthesia. There were no epineural adhesions or evidences of extraneural compression. The epineurium appeared thickened over a distance of 3 cm. This segment was somewhat whiter than a normal nerve trunk and to palpation was definitely firmer. Faradic stimulation above and below the lesion produced tingling in the thumb and index finger, and stimulation of the triceps branch produced slight contraction.

On follow-up examination fifteen months after the injury, there was no sensory change. Atrophy had not progressed, and function of the fingers and elbow was as before. There was slight return of motor function in the extensors of the wrist.

Case 4.—F. C., a 26 year old white woman, received penicillin in wax as part of ambulatory therapy for an infection of the upper part of the respiratory tract. At the time of the treatment she removed her coat, held it in her left hand and pulled her sleeve up with her right hand. The penicillin was injected intramuscularly in the posterior aspect of the left arm, at which time a sudden severe aching pain associated with tingling paresthesia was noted over the distribution of the radial nerve as in case 3. At the instant of injection, her coat fell from her hand and a wrist drop was noted. Paresthesia persisted for three months in the first web space.

At the time of examination three months after the injury, loss of function of the extensors of the wrist and fingers and of abduction of the thumb existed. Faradic stimulation produced no response. The muscles were atrophic and the radial tendon response on the left was absent, but present (2 plus) on the right. Sensory changes were noted over the sensory domain of the radial nerve. At operation with local anesthesia the nerve was found flattened and surrounded by a thickened epineurium. Embedded in the epineurium were many globules of what appeared to be oil or wax. External neurolysis was done, and further examination revealed what appeared to be a normal nerve segment. Faradic stimulation of the radial nerve as it emerged from behind the humerus caused paresthesia in the thumb and contraction of the brachioradialis muscle. No other muscles responded.

When examined ten months after the injury, the atrophy was much more pronounced and there was no improvement in the complete motor disability or sensory loss.

In essence, these patients exhibited what appeared to be a toxic reaction to large concentrations of penicillin injected into or adjacent to major peripheral nerve trunks. This antibiotic-induced neuritis was characterized by intense immediate pain radiating distally along the course of the affected nerve segment, a complete, but in 2 cases rapidly regressing, sensory loss and an early motor disability that, in 2 instances at least, became a chronic and static disability. The reaction bears no resemblance to any of the well known traumatic sequelae of procaine anesthesia, for instance. The reaction may be more intense in the presence of a vehicle such as wax, but is probably not wholly dependent on such a vehicle. The operative observations in 2 cases suggest an intraneural lesion and do not indicate extraneural compression. The clinical picture predicates a more profound alteration in motor axones. The cases have much in common with those reported by Kolb and Gray. The delayed onset in their cases may have been due to slow infiltration of the toxic agent from a distance or may have occurred during the course of treatment. The neuropathologic changes in experimental animals are now being studied in this laboratory.

## CONCLUSION

Four cases of injury to a major peripheral nerve by penicillin injections are reported. In view of the established toxicity of this antibiotic in other parts of the nervous system, it is assumed that this neuritis represents a specific reaction to a high concentration of penicillin.

# EXTRADURAL HEMATOMA IN INFANCY AND CHILDHOOD

FRANC D. INGRAHAM, M.D.
JAMES B. CAMPBELL, M.D.
and
JONATHAN COHEN, M.D.
Boston

The formation of extradural hematoma is well known as a result of head injury in adults.[1] It is much less frequently recognized that extradural hematoma often occurs in infancy and childhood, the literature being confined to isolated case reports. In fact, such authors as Munro and Maltby,[1b] Peet[2] and Gurdjian[1c] stated that the lesion is a rarity in the pediatric age group. Our experience indicates that the occurrence of extradural hematoma in infants and children is more frequent than the literature suggests, 20 instances being found among approximately 1,000 cases of head injury in patients below the age of 12 years. Since the clinical signs usually differ greatly from those seen in adults, the extradural hematomas may be easily overlooked. Prompt neurosurgical treatment is life saving and has been associated with a low mortality rate. For these reasons, we summarize the material of a pediatric neurosurgical service in dealing with this lesion.

In adults, extradural hematoma formation is suggested by a history of trauma to the head with immediate but brief loss of consciousness, followed by a lucid interval and a second loss of consciousness. Munro and Maltby,[1b] among others, stated the belief that a fracture of the skull is always present. McKenzie[1a] emphasized the progression of signs: drowsiness gradually changing to coma and weakness to hemiparesis. The dilatation of the pupil contralateral to the hemiparesis also is progressive, as are the signs of increasing intracranial tension as reflected by changes in pulse, respiration and blood pressure. The spinal fluid is under increased pressure but shows no abnormalities in cellular content.

The possibility of extradural hematoma formation must be kept in mind as clearly in dealing with infants and children with recent trauma to the head as with adults. The age incidence in our series is shown in figure 1. A little over half were infants, and the rest were evenly distributed to the age of 12 years. In both groups, the incidence was twice as great in male as in female subjects.

[2] Peet, M. M., in Brock, S.: Injuries of the Skull, Brain and Spinal Cord: Neuro-Psychiatric, Surgical and Medico-Legal Aspects, ed. 2, p. 123, Baltimore, Williams & Wilkins Company, 1942.

The clinical observations in extradural hematoma in infants and children are different from those due to the same lesions in adults. In our group of 20 patients below the age of 12 years, each with an extradural hematoma, only 3 showed an initial loss of consciousness with subsequent lucid interval, while 17 had a latent period between injury and the development of stupor. Seven of the 20 patients ultimately became comatose, including the 3 with initial loss of consciousness followed by a lucid interval. Swelling of the scalp at or near the site of injury is a common sign. It usually, but not necessarily, overlies a fracture of the skull. Of great importance in diagnosis is the progression of drowsiness to stupor or coma, especially when accompanied with circulatory and respiratory changes suggesting compression of the medulla or with localizing neurologic signs. Hemiparesis was usually noted. The Babinski sign and dilatation of the pupil on the side of the lesion were frequently encountered, but convulsions and signs of cranial nerve involvement were rare. There was a decerebrate postural pattern in 5 patients. Jefferson[3] suggested that this phenomenon results from the disturbance of circulation to the higher centers caused by their displacement and compression by the hematoma, which permits the midbrain reflex arcs to be released from cortical inhibition. It must be borne in mind that cortical contusion or laceration, as well as intracortical hematoma or acute subdural hemorrhage, may produce these same neurologic signs. Precise diagnosis must sometimes await operation.

The blood loss in an extradural hematoma has systemic effects in infants not found in adults. Blood loss of 100 to 150 cc. is sufficient to produce profound shock in an infant, and extradural hematomas often involve bleeding of this degree or even more. As much as 400 cc. has been found. Four infants in this series, with presumably normal red blood cell counts and hemoglobin levels before injury, showed preoperatively red blood cell counts from 2,000,000 to 3,700,000 with corresponding hemoglobin levels. For this reason, pronounced anemia and shock following a head injury in an infant may point to intracranial bleeding, even though there are no abnormal neurologic signs, unless the anemia can be explained by trauma to other viscera. Since infants with acute blood loss into the extradural tissues do not always show bradycardia and increase in pulse pressure, decision, in these circumstances, must be guided by the degree of shock and by the onset and progression of neurologic signs.

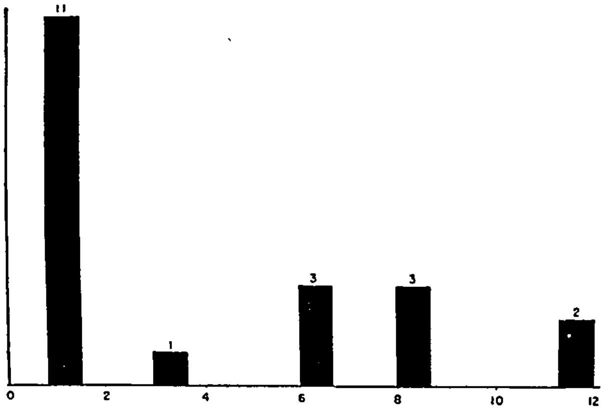

Fig. 1.—Graph showing age incidence. In the series of 20, there were 14 male and 6 female patients. (The horizontal row of figures shows the age in years, and the figures above the bars shows the number of patients in each age group.)

Lumbar puncture was performed in 12 of the 20 patients. In 8 there were no abnormalities in cellular content. In 4, appreciable numbers of red blood cells were found. In 1 of them there was also a greater number of white blood cells than could be accounted for by bleeding alone. This led to a tentative diagnosis of infection in spite of the history of trauma. The expandable skull of this 9 month old infant had evidently been able to accommodate the clot long enough for polymorphonuclear leukocytes to appear in the cerebrospinal fluid in response to irritation of the meninges. The pressure of the cerebrospinal fluid in 5 patients ranged from 230 to 450 mm. of water, but was normal in 4 others. We are unable to explain the normal pressures. Munro and Maltby[1b] recorded similar observations without obvious explanation.

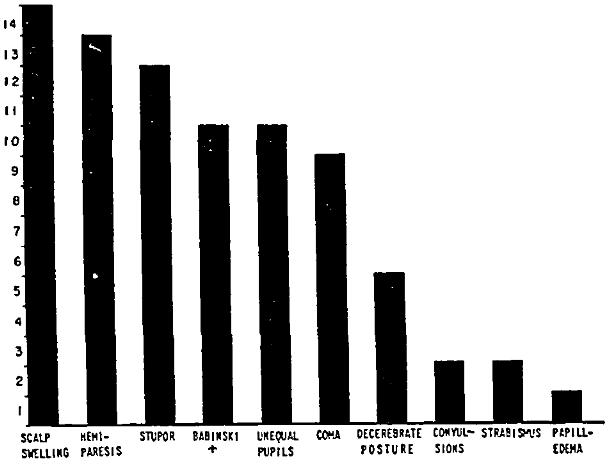

Fig. 2.—Graph of common physical observations. (The vertical column of figures at the left shows the number of patients.)

Fractures (fig. 3) were demonstrated in 12 of the patients by roentgenograms or at operation, while none was found in 8 patients. Diastasis of sutures was demonstrated roentgenographically in 12 patients, 6 of whom had no evidence of fracture. In addition, a decided diastasis of the squamosal suture was encountered at operation in the absence of fracture.

## MECHANICS OF EXTRADURAL HEMATOMA

The factors chiefly responsible for deflection of blows to the head are the looseness of the attachment of the skin and galea to the cranium, the multidirectional mobility of the cervical part of the spine and the curvature of the skull. In children, the open sutures and elasticity of the cranial bones also help to dissipate the force of trauma and protect the intracranial contents.

Until their final closure, the sutures are regions of fusion of the outer periosteum and dura. The dura at this age is loosely attached to the central parts of the bones of the vault, fixation being firm only near the edges of the bones and along the sutures. In order for changes in skull contour to take place as growth progresses, there is resorption at the center of the bones and concomitant dilatation of the meningeal blood vessels. This process is most active during the first two years of life, when the increase in brain size is greatest, but continues until the contour of the adult skull has been established, usually at the age of 8.

---

[3] Jefferson, G.: Bilateral Rigidity in Middle Meningeal Hemorrhage, Brit. M. J. 2: 683-685, 1921.

Since the fibrous and osseous layers of the cranium have different coefficients of elasticity, compression or expansion will set up shear stress at the junctions of the layers. This leads to tension on and ultimate rupture of blood vessels. Potential spaces for the collection of extradural hemorrhage exist at the centers of the frontal, parietal and occipital bones, where the attachment of dura to skull is less firm than at the edges. In this series, there were 4 patients with extradural hematomas limited to the potential parietal space and 1 to the frontal space. The clot extended beyond these limits only when a fracture crossed a suture. This mechanism may account for our 8 cases of extradural hematoma formation in the absence of fracture. The anatomic relationships of skull and dura explain loculation of the clot beneath the parietal and frontal bones.

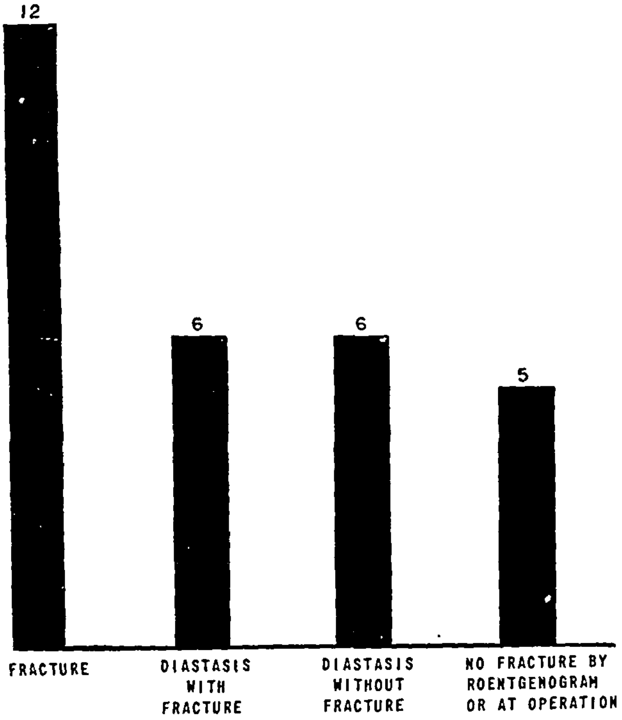

Fig. 3.—Incidence of skull fracture and suture diastasis (no preoperative roentgenography was done in 3 cases). (The figures above the bars show the number of patients.)

SOURCE OF HEMORRHAGE

Jones[4] in 1912 drew attention to the fact that the middle meningeal artery is not the sole source of hemorrhage into the extradural space. He found that extradural hemorrhage is frequently produced by rupture of the thin-walled veins of the dura, both those accompanying the middle meningeal artery and the tributaries of the dural sinuses. In the adult, the middle meningeal artery is the more frequent source. This mechanism is sometimes the cause of extradural bleeding in children, but is less important than injury to veins since the meningeal grooves are shallow at this age and gradually deepen as time goes on.

PROGRESSION OF SIGNS

If the total traumatic force is not expended on the skull and its coverings, the residual force will be brought to bear on the brain itself. Cerebral concussion, contusion, laceration, subdural hemorrhage or intracortical hemorrhage, or any combination of these, may result from the action of the residual force.[5] The immediate loss of consciousness seen in head trauma may result from a cerebral concussion or from the other conditions herein listed. An initial loss of consciousness occurred in 3 of our 20 cases, indicating that the pliable skull of infancy and childhood may dissipate relatively more force than the adult skull with rigid bone and closed sutures. The occurrence of a latent period between the traumatic episode and the advent of neurologic and of increased intracranial pressure signs is therefore of greater importance in diagnosis than the usual syndrome seen in adults. The length of the latent interval is dependent on the caliber and type of vessel lacerated and on capacity of the pliable skull to accommodate the clot by stretching the fibrous sutures and lines of fracture. If, however, the rate of clot formation exceeds the compensatory increase in cranial volume provided by the pliable calvarium, compression of the brain occurs.

Pressure is built up in the latent period, which has varied from fifteen minutes to seven days in this series. The appearance of signs at the end of a long latent interval constitutes just as much of an emergency as it does after a short one. Operation may be deferred on a patient in shock if the extradural bleeding drains into the subgaleal space by means of a decided diastasis or a fracture line. The vessels of the outer periosteum as well as the diploic circulation add to the subgaleal collection of blood. The total accumulation of blood in extradural hematomas in this series varied from 100 to 400 cc. If the patient is an infant or small child, the loss of this amount of blood may lead to profound shock and must be promptly replaced. In these circumstances several days may be allowed for recovery from the cerebral injury usually associated with the hematoma. Operative removal of the clot, subgaleal and extradural, may then be undertaken with decreased mortality and morbidity rates.

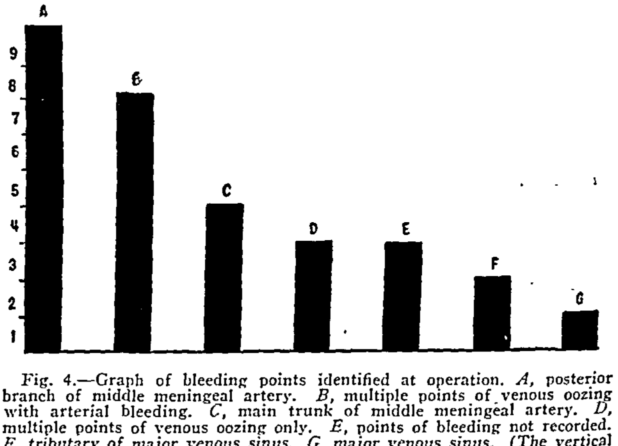

Fig. 4.—Graph of bleeding points identified at operation. *A*, posterior branch of middle meningeal artery. *B*, multiple points of venous oozing with arterial bleeding. *C*, main trunk of middle meningeal artery. *D*, multiple points of venous oozing only. *E*, points of bleeding not recorded. *F*, tributary of major venous sinus. *G*, major venous sinus. (The vertical column of figures at the left shows the number of patients.)

PREOPERATIVE CONSIDERATION

Roentgenologic examinations and lumbar puncture are useful adjuncts in diagnosis, but neither should be carried out if the patient is in shock. In many instances, correlation of the history with the neurologic examination presents sufficient evidence of progression of signs to warrant trephining. Therefore, measures to combat shock are instituted and the operative procedure is carried out as soon as possible. Palpation of localized swelling often indicates the approximate position of the fracture. This becomes more obvious if an ecchymosis is seen when the head has been shaved. As soon as a patient with a severe head injury is admitted, the patient's blood is matched with blood in the blood bank. This has proved to be a most worth while measure, because blood loss in the pediatric age group is less well tolerated than in older subjects. A polyethylene tube is inserted in the exposed saphenous vein while the patient is still in the emergency ward.

[5] Denny-Brown, D., and Russell, R. W.: Experimental Cerebral Concussion, Brain **64**: 93-164, 1941.

### OPERATIVE PROCEDURE

After complete shaving of the head, the skin of the suspected side is prepared with suitable antiseptic solutions and so widely draped that the exposure, if necessary, can be carried from the foramen spinosum to the superior longitudinal or lateral sinus. Should ligation of the external carotid artery be contemplated, it is advisable to include the neck in the preparation and draping. Local infiltration of 0.5 per cent procaine hydrochloride with epinephrine is used on all patients. Open drop ether anesthesia is often necessary as a supplement if the patient is restless or struggling. The incision for the initial burr hole is placed so that it can be extended to expose the temporal bone for a classic subtemporal decompression. If the clot is in the frontal region, the bone flap is turned down in the manner originally described by Cushing.[6] In small infants, it has been more expedient on several occasions to use heavy scissors in making the bone flap. On discovery of a clot, a blood transfusion is started, if it has not already been instituted as a resuscitative measure. If the bleeding is arterial, tantalum clips or silk sutures are used for hemostasis. Absorbable hemostatic materials, judicious endothermy coagulation or clipping is used for venous sources of hemorrhage. In most cases the brain expands rapidly to its normal volume. At this point it is well to open the dura in order to inspect the subdural space and cortex, so as to determine whether there is subdural bleeding or cortical damage. It has not been necessary in this series to leave a dural decompression unless extensive cortical damage has been apparent. All layers of the wound are closed with silk. If a large dead space remains, a drain from the dura is left in place for twelve to sixteen hours and sulfadiazine and penicillin are given prophylactically for forty-eight hours. Burr holes are done on the opposite side of the calvarium at a later date in children in order to determine the presence or absence of a contralateral clot. In infants, subdural taps through the open suture lines yield sufficient evidence to establish the presence or absence of a subdural clot.[7]

Postoperatively, general supportive care is given. Lumbar punctures are carried out daily if the initial spinal fluid examination reveals evidence of bleeding into the subarachnoid space. This procedure is continued until red blood cells in the spinal fluid count fall below 500 cells per cubic millimeter. Lumbar punctures are continued if there are signs of increased intracranial pressure, hyperthermia or a change in neurologic signs. The pressure is customarily reduced by one-half at each lumbar puncture. Most of the infants and younger children tend to regenerate bone over their areas of bony decompression within a year.

### MORTALITY

Eighteen patients are living and 2 dead. One of the patients who died had severe cerebral laceration and thrombosis of the superior longitudinal sinus. The other died with hyperthermia. Of the 18 surviving patients, only 1 had a neurologic deficit. This patient has had one convulsion and has a persistent mild hemiplegia. It is interesting to note that this patient had decerebrate postural patterning before operation.

### SUMMARY

Extradural hematoma proved by operation occurred twenty times in a series of a little over 1,000 pediatric patients treated for head injury. The differential diagnosis is discussed. The signs manifested by the patients in the series are listed and considered in regard to the mechanics of the skull. The indications for trephination are given. This is the only certain method of diagnosis and of adequate treatment. The operative procedure is outlined. There were 2 deaths in a series of 20 infants and children.

## THE PROBLEM OF MEDICAL CARE FOR NAVAJO INDIANS

MICHEL PIJOAN, M.D.
and
CHARLES S. McCAMMON, M.D.
Fort Defiance, Ariz.

Recently, considerable comment has been made regarding the health services rendered to Navajo Indians, apparently because the Navajo tribe (numbering approximately 65,000 persons) is the largest Indian tribe in this country and the health services rendered are far from adequate. Several factors enter into this: that the geographic domain of this tribe is large, that travel is difficult, that their culture differs from ours and that the few physicians ordinarily employed have little or no conception of cultural differences or are insufficiently trained to carry out medical inquiry and care of the sick. These, and other similar or contingent criticisms, appear warranted. But statements made with reference to the scarcity of certain diseases among the Navajos are based on insufficient evidence or the lack of diagnostic procedures; such concepts are the cause for much speculation and concern and should be reconsidered in the light of modern medicine.

Generally, physicians have been taken from civil service lists, given no training in colonial field medicine or in the cultural aspects of the problem and sent to field medical duty. These physicians, with few exceptions, are usually poorly qualified, are graduates of inferior medical schools and have received a minimum period of hospital duty required by civil service. In certain instances mission hospitals have given much better service. A complex situation has arisen wherein concepts and ideas have generally become distorted and one sided. One of the features that is most lacking is that there is no connection between the programs and the medical schools. Without the continued spirit of inquiry and challenge of academic medicine, such field programs have a tendency to fall into dull, uninspired routines. Without a pathologist, a suitable laboratory association, without medical school affiliation, without special training of field physicians (a matter that the London School of Tropical Medicine and Hygiene considers of great importance), the medical program among Indians can be only what it is.

From the Health Division, United States Indian Service, Fort Defiance, Ariz.

Chief of Medicine (Dr. Pijoan) and Medical Officer in Charge (Dr. McCammon), Navajo Medical Center.

The opinions and views of this article and those of the authors are not necessarily those of the United States Indian Service.

### PRESENT FACILITIES

Cognizant of this situation last October 1948, the Navajo Indian administrators endeavored to change the type of medical care. First they established a sound working staff at their central hospital and added the diagnostic facilities needed.[1] The men chosen were not necessarily from civil service lists, but did meet, obviously, the civil service requirements. These men had sufficient training to direct adequately a special service. Thus, the base hospital today has a staff consisting of a surgeon in chief, a physican in chief and the other chiefs of staff, such as a pediatrician, a gynecologist, an obstetrician and a pathologist; a dispensary physician, a specialist in eye, ear, nose and throat and a specialist in tuberculosis. To this group is added adequate laboratory personnel. Regular staff meetings are held, papers are read and clinical pathologic conferences introduced. There are two committees, a library committee and a drugroom committee, the first dealing with journals and textbooks being purchased for the library and the second group endeavoring to place the choice of drugs on a scientific basis. The hospital is equipped to carry out special studies, such as metabolism, electrocardiography, roentgenology and bacteriology.

Since July 1, 1948, there have been 2,171 admissions to the hospital service; the outpatient department has had 5,488 new cases with 8,038 repeated visits. In March 1949, the outpatient department reported 906 new patients and 1,514 repeated visits. These figures far exceed any in previous years. It becomes at once apparent that such a number of visits and admissions is beyond the capacity of the staff described and that many of the patients should have been taken care of in the smaller field hospitals on the reservation. Up to April 1 of this year, the pediatric service alone admitted 647 children, and the remainder of the admissions, 1,424 cases, were distributed among the other services.

In the medical service, with about 450 admissions, there were 53 patients with intrinsic cardiac disease varying from pericarditis to mitral stenosis; malignant diseases in all services, exclusive of the outpatient department, occurred in 19 patients. Since many assume that neoplastic disease does not occur among the Navajo Indians, these cases are listed as follows:

| | |
|---|---|
| Myxosarcoma with | 1 |
| Carcinoma of the | 1 |
| Epidermoid carcinc | 1 |
| Carcinoma of the cervix, grade III | 2 |
| Adenocarcinoma of the biliary tract | 2 |
| Carcinoma of the uterus, grade III | 2 |
| Carcinoma of the prostate | 2 |
| Papillary tumor urinary bladder | 1 |
| Carcinoma of the stomach | 1 |
| Tumor of the pituitary | 1 |
| Leiomyosarcoma of the urinary bladder | 1 |
| Epidermoid carcinoma of the conjunctiva | 1 |
| Multiple myeloma | 1 |
| Lymphosarcoma cervical and mediastinal lymph nodes | 1 |
| Seminoma with metastases | 1 |

It is at once obvious that both heart disease and malignant disease are present among Navajo Indians and that as the year continues new cases will appear.

Among the 2,171 admissions there were 120 deaths, 10 of which were still births, 43 due to terminal tuberculosis and 48 due to infant mortality. Just within the past few months has the autopsy record been at all commendable, with 9 autopsies having been performed. However, it is to be noted that biopsy material is constantly being submitted to the pathologist, a fact which may in small measure compensate for the low record of autopsies.

For the sake of brevity the surgical service record is shown in the table.

The procedures shown in the table are divided between the gynecologic service and the general surgical service. There were 206 live births in the obstetric service during the period described.

This, then, has been the gradual evolution of the base hospital, the Navajo Medical Center. An affiliation with a medical school is strongly needed. There is a host of unsolved problems—the cause of the diarrheas, the adequacy of the treatment of trachoma, the epidemiologic aspects of trachoma, the nutritional situation of the Navajo, intestinal parasitism, atypical pneumonias, anemias and tuberculosis.

With reference to tuberculosis, the x-ray mobile unit reported that, out of 16,000 persons examined, 1,859 showed evidence of progressive pulmonary tuberculosis. Yet the sanatorium at Fort Defiance for Navajo Indians has a capacity of only 100 beds. This year's admissions to the sanatorium totaled only 67 patients. Even though the BCG program will alter the course and susceptibility of persons to the disease, the crowded dwellings (hogans) and the presence of open lesions, which yield large numbers of organisms, still prevails and will continue to create the disease in susceptible persons. The base hospital has referred 68 patients to the sanatorium, a number which exceeds those admitted to that institution.

*Surgical Services*

| Month | Major Procedure | Minor Procedure | Casts |
|---|---|---|---|
| October 1948 | 6 | 33 | 3 |
| November 1948 | 8 | 53 | 9 |
| December 1948 | 12 | 39 | 12 |
| January 1949 | 10 | 51 | 14 |
| February 1949 | 13 | 40 | 5 |
| March 1949 | 15 | 61 | 3 |

*Field Service.*—The field service now has a hospital at Tuba City, one at Shiprock, one at Winslow and one at Crownpoint. These hospitals have from 30 to 50 beds each and contain a surgical theater, dispensary and laboratory. They should act as the first clearing station and maintain public health programs within their area. An adequate number of field nurses should be obtained for these isolated areas (Winslow is not isolated). The field nurse program has just begun to develop (only two field nurses were present in early 1948; now there are eleven nurses). The program is as yet in its infancy, but plans for a well coordinated field service are being made, which will include immunization and other matters pertinent to field duty. Once again the choice of the physician in these districts is of paramount importance, and the program at Tuba City (Western Navajo area) and Crownpoint (Eastern area) are now showing progress because the physicians are sufficiently qualified to direct such programs.

---

[1] One year ago, there was only one dentist for the entire reservation; today there are three full time dentists. At present there are two sanitarians and one sanitary engineer. The hospital nursing staff for the entire reservation, excluding the field nurses, numbers forty-nine registered nurses. The entire program is directed by Dr. Henry W. Kassel, Director of Health, under the general organization in which James M. Stewart is superintendent.

COMMENT

It is possible that further small hospital units will have to be developed. So far the field service has been the neglected service; this explains, in part, the heavy load of patients coming to the base hospital at Fort Defiance. Actually, the base hospital should be used for diagnostic purposes, treatment in selected cases, special surgical procedures and research. The field hospitals should send to the base hospital any patient who they feel requires special attention.

The tuberculosis situation needs immediate attention, and facilities should be made available for the care of the tuberculous patient. Here, again, affiliation with institutions specializing in this type of medicine is of supreme importance.

To date the problem of giving medical care to the Navajo Indians is a challenging one and deserves careful study and effort rather than the emotional approach used by many persons. The formula for rendering medical aid to Navajo Indians is by no means solved—advice, criticism and help are solicited and, if given with careful thought, will be greatly appreciated. It is to be remembered that the Navajos have a rich and creative culture and that any program developed must in great measure consider their way of life.

# TREATMENT OF PARAPLEGIA RESULTING FROM TRAUMA TO THE SPINAL CORD

L. W. FREEMAN, M.D., Ph.D.
Indianapolis

*(Concluded from page 958)*

4. *Blood.*—As already indicated, the first weeks after spinal cord injury are marked by an extremely abnormal blood picture. In the first twenty-four hours there begins a series of poorly understood changes. Serum protein begins to fall sharply, followed later by a drop in hemoglobin, and later by a decrease in red blood cells. At the end of the first week, the serum protein may reach levels below 5.0 Gm. per hundred cubic centimeters, the hemoglobin below 10 Gm. per hundred cubic centimeters and the red blood cells below 3,500,000 per cubic millimeter. In the presence of decubiti and bladder infection, these low levels are usually reached, and the albumin-globulin ratio is reversed. If decubiti are not present at this time, they are most likely to develop unless careful turning is carried out. It is far better to anticipate these changes by the administration of whole blood, calculated as 1 pint (473 cc.) for each 0.5 Gm. that the hemoglobin level is found below 14 Gm. per hundred cubic centimeters. Decubiti are much less a hazard, and, more important, the patient resists infection better, his appetite improves and his general well-being is enhanced. To attempt to combat these changes by the intravenous administration of protein digests,[38] plasma or serum is futile. These infusions must be run almost constantly and do not remain in the blood stream long enough to alter the picture greatly. Then, too, each of these substances leads to sensitization.

In addition to these substances, decided diminutions in vitamin levels, especially ascorbic acid, will often be found. The general tendency to the routine administration of various vitamins cannot be condoned. In some military hospitals, before meal medication consisted of three full 1 ounce (28 Gm.) glasses of vitamins to each paraplegic patient, almost too much for the patient to consume as the main course of the meal. When deficiencies are indicated by low levels in the blood, the necessary elements should be administered hypodermically until food intake is normal or above, at which time they should be discontinued. It is unlikely that supplementary vitamin D is ever warranted in otherwise normal adults. Furthermore, until more is known of the exact nature of the mechanisms of calcium excretion in the recumbent patient, any agent which is likely to increase calcium absorption from the intestines should be avoided. Vitamin A has been implicated in stone formation.[39] With the factors of recumbency, stasis and infection already present, a deficiency of vitamin A is unlikely to assume much importance. In a large group of "rapid stone formers," no significant difference in the rates or numbers were seen in a group given high supplements of vitamin A as compared with a control group given no supplements. Vitamin C should be given when deficiency can be demonstrated, on the basis of reports that deficiency leads to delayed healing.[40] No deleterious effects from its administration have been noted, but when only traces were found in the blood, as much as 1,000 mg. were needed daily by mouth or 500 mg. by hypodermic injection to restore normal levels. The tendency to withhold citrus fruits from these patients on the basis of the resulting alkaline tide is unwarranted,[41] for these substances serve as a palatable source of fluid, citrate and vitamin C. There is no reason why the B complex vitamins should be given, and yet the repeated demonstrations of their relation to the central nervous system would indicate that they can be given as drugs with benefit,[42] if not as vitamins alone.

The level of nonprotein nitrogen of the blood is found to rise during the early stages after injury and in infections of the upper part of the urinary tract. A rise of the creatinine level implies serious renal damage. Therapy should precede such changes. Urinary calcium will be found to increase sharply within the first week of recumbency and will reach a plateau two to three times normal until ambulation is started, and then it slowly returns to approximately normal levels.[43] It is rare to find any elevation in blood levels of calcium, phosphorus or phosphatase during these striking changes.

It is apparent that the leukocyte count shows a high normal or slightly high level. This usually results from the presence of subclinical bladder infection alone. Mention is made only to serve as a basis for later discussion.

5. *Other Features.*—Considerable care should be exercised with respect to the nails, and hygiene should be superb. Bed baths are at best inadequate, and the perineum is often neglected, especially in male patients. These should be checked frequently.

Among the complications already mentioned which might arise in the early stages is epididymitis. It is singled out for special consideration because of the high frequency with which patients with this disorder are operated on for acute appendicitis. The symptoms of nausea and vomiting are frequent. Lower quadrant rigidity (this is before the return of reflexes) and rebound tenderness are usual in patients with lesions below the tenth dorsal dermatome and are found in patients with high lesions as well. Coupled with a moderate elevation of temperature and elevation of the leukocyte count, the diagnosis of appendicitis is appealing. However, an examination of the epididymis readily reveals the source of the difficulty, and local treatment coupled with systemically administered penicillin gives prompt resolution. In the many patients seen, of whom only 17 came to autopsy during the first year of treatment, only 1 showed appendicitis, and in this case the cause of death was massive empyema. However, at least 30 of these patients underwent removal of the appendix after their injury, with no indication on the records that the appendix had been abnormal in any way, and with most having shown full blown epididymitis the day after operation. This should not take attention from the fact that appendicitis is as likely to occur in these patients as in any other.

Pain is deserving of special attention. If the patient suffers from root pain which is not relieved by traction, the possibility of relief by surgical decompression of the affected roots should be considered, provided that the procedure can be undertaken with relative safety. If the pain is not of the root type, it rarely requires medication of any kind. Certainly, morphine or its derivatives and substitutes should never be given unless the patient's personality structure is essentially healthy. The grounds for this statement include the undesirability of depressant drugs like morphine in many neurosurgical cases and the extreme vulnerability of the paraplegic patient to addiction to drugs.[44] Sparing use of codein is justified in a few patients only. On the other hand, intramuscular or oral administration of phenobarbital is tolerated well and serves the same end. It is often useful, for the patient usually is greatly disturbed after discovering his disability. However, adequate support by psychotherapy, together with adequately planned occupational activities, will usually obviate the need for phenobarbital.

## LATE CONSIDERATIONS

1. *Pain.*—As just mentioned, pain must be dealt with vigorously. It is difficult to determine just how severe pain is in the early stages, although acute root pain has been reported to be severe enough to kill.[14c] Aside from the early period, pain usually appears at about the sixth week following injury. In injuries of the cauda equina, this is likely to be of a root type and gradually increases in severity until the very life of the patient is in jeopardy.[44] Decompressive laminectomy is not highly successful at this time, but should be tried first. If pain persists, a bilateral section of the anterolateral spinothalamic tracts high enough to insure a level of thermanesthesia and analgesia above the fourth thoracic dermatome should be done.[45] The principal objection to a cordotomy at a lower level is that all too frequently these patients have a "sympathetic" type of pain in addition to root pain, and to secure relief from all pain the level must reach above the fourth thoracic dermatome. Another distinct advantage to cordotomy at this level is the relative infrequency of postoperative girdle pain. For the "sympathetic" type of pain, it is rare that any procedure is necessary. Of the numerous complaints of the paraplegic patient, this constant burning type of pain is prominent most frequently when there is preoccupation with the disability, or after all other complaints have been resolved. Most of these patients, and they comprise a large percentage of the total, can tolerate this pain well enough if they are active. The similarity of some of these complaints to those of vascular disease and causalgia has prompted some to remove the sympathetic ganglions. No case has been seen in which results resembled in any way those obtained with vascular injuries and causalgia.[46] Murphey[47] and Mayfield,[48] however, have expressed the opinion that relief can be obtained by sympathectomy, but their patients have failed to obtain long-lasting relief. Perhaps the extension of the sympathectomy upward to include the upper thoracic ganglions might provide complete relief, which has not been afforded by low thoracic and lumbar procedures. Experiments now in progress[49] indicate cross-over of pathways and higher entrance in the spinal cord of painful impulses of a vascular origin than is generally believed. It must not be forgotten that the site of injury is the spinal cord or its nerve roots, leaving inflammatory and glial reactions as a possible source of pain. Finally, pain may be almost totally psychic, as implied in the remarks about medication. The main point for differentiation resides in the fact that the patient is unable to describe the pain accurately, in contrast with those suffering from root pains, and is inconsistent in his description as to type and location (which is not the case with the patient complaining of "sympathetic" pain). Therapy consists of reassurance or, when necessary, more vigorous psychiatric therapy. Many psychiatrists will evade calling the pain psychic or will declare that the patient has adequate damage to his central nervous system to account for it. The patient with a personality which requires much support may be overly sensitive to pain,

and the institution of indicated psychotherapeutic procedures may decidedly reduce the patient's reaction to pain. Certainly, both the physical and psychologic damage should be given careful consideration.

Numerous drugs have been tried on various types of pain, with the majority failing to accomplish much in the way of relief. Among these were cobra venom, curare, intravenous administration of alcohol and intravenously given procaine hydrochloride. No patient obtained lasting benefits, although enough encouraging responses were seen to warrant their further trial. Of more significance than these procedures were the various modes of nerve blocks. In an occasional patient, trigger zones can be found and relief sometimes follows massive local infiltration with very dilute procaine hydrochloride solutions. Repetition of the procedure sometimes gives lasting relief. Injection of appropriate nerve roots has also yielded occasional good results, especially when repeated. A few cases of relief for appreciable periods of time have resulted from sympathetic ganglionic blocks for the sympathetic type of pain. Continuous spinal anesthesia has been similarly successful, but is hazardous. Continuous extradural blocks have given startlingly good results in several patients. One might say that every avenue of conservative treatment should be used if the patient's health is not declining, but radical measures should then be instituted. It is certainly not true that root pain "dies out" [50] and that cordotomy is unsuccessful. The writings of White,[51] Hyndman,[45c] Kahn [45d] and many others are in complete disagreement on this point with the views expressed by Davis and Martin.

In patients who have suffered pain for prolonged periods, it might be advantageous to perform a limited prefrontal lobotomy,[51] to excise part of the sensory cortex.[52] With rehabilitation as the primary aim, every effort should be made to make rehabilitation possible.

2. *Spasms*.—Flexor spasms are an almost constant occurrence in patients with injury to the spinal cord,[53] and only those with destruction of the distal segments show continued flaccidity. Obviously, patients with injury of the cauda equina will not show spasticity unless the cord is damaged, and then the spasms are limited in nature. Reflexes begin to appear before the sixth week and are often of the withdrawal type by that time. If voluntary motion is to reappear, it will have done so before this time in the majority of patients. It might be noted that it is not uncommon for the patient, his nurse or even his physician to be misled by reflex movement of the paralyzed extremities. Early the appearance of such movement is often misinterpreted as the beginning of the return of voluntary motion. Aside from this, it is of importance to note the time of appearance of such phenomena as the Babinski response (dorsiflexion of the great toe, often with spreading of the toes). When this phenomenon or any other reflex action is seen within hours after injury to the spinal cord, it can be assumed that the spinal cord lesion is incomplete. This might alter the opinion somewhat as to the type of therapy. However, this response (Babinski) or any other reflex response has no significance as to prognosis at any other time. Extensor responses have been widely heralded as indicative of incomplete lesions.[54] However, it is not unusual to find extensor responses in the presence of complete anatomic transection of the spinal cord.[55] This point has not attracted sufficient attention and must be stressed. To stray for a moment, an amusing incident might be cited. A patient was referred to the psychiatric service largely for resolution of the question of the advisability of prefrontal lobotomy. He showed a combination of traumatic paraplegia, pain and paranoid schizophrenia. It was decided that "radical" neurosurgery should await "conservative" methods, such as insulin shock therapy. No objections were raised, and the suggestion that the patient be saved for presentation to a consultant at a demonstration clinic was agreed on. After a careful and detailed presentation by one of the residents, the visiting consultant made a brief examination of the patient. He then issued forth with such statements as: "The presence of reflexes indicates that the lesion of the spinal cord is incomplete. . . ." Shades of the old Bastian-Bruns law, which stated that after transverse lesions of the spinal cord in human beings, reflexes are abolished and never reappear.[56] The consultant's opinions were scored in red and promptly disregarded. It is almost inconceivable that advocates of concepts antedating "laudable pus" are still with us, but their influence is still strong enough to require comment.

Once flexor spasms begin, their course is largely determined by many factors. Not the least of these is the presence of complications such as decubiti or infections of the urinary tract. It is likely that either of these will initiate sufficient afferent impulses to extinguish the pattern of extension. The more primitive pattern of reflex withdrawal will obtain, with the semifinal stage being represented by paraplegia in flexion.[2e] If the patient is kept in good health, extensor reflexes will appear in almost every patient with a complete transverse section of the spinal cord. Thus, a favorite prognostic sign of old loses much of its significance. The often-heard phrase that flexor spasticity wears out after a year can hardly be passed on without almost prohibitive reservations. That reflexes will not become worse after a year in a healthy paraplegic patient is a fact. However, once flexor reflexes become well established, they diminish only to a basic minimum. This occurs as the decubiti are healed and as the bladder becomes automatic and free of infection. Just what this minimum level of flexor spasticity will be is an individual matter. From the point of view of a wheel chair existence, most will have an inconsequential amount of flexor spasm, if they ever had flexor spasm at all. However, for a full program of rehabilitation, even minor flexor spasms may prove to be harmful. Each patient must be watched carefully for such impeding spastic contractions as strong adduction or hip flexion. These can be corrected by peripheral nerve section.[57] In the neglected patient, when paraplegia in flexion is threatening the very life of the patient—as it almost always does—the anterior spinal roots from the eleventh dorsal through the first sacral (and possibly the second sacral) should be sectioned.[58] The value of this procedure is illustrated by the following instance.

[56] Bastian, H. C.: On the Symptomatology of Total Transverse Lesions of the Spinal Cord with Special Reference to the Condition of the Various Reflexes, Med.-Chir. Tr. 73: 153-217, 1890.

H. J., a young Negro soldier, was admitted with a lesion at the level of the sixth dorsal segment, resulting from a gunshot wound about nine months before admission. Examination showed no neurologic change from that seen in the original examination, which had shown a complete transection. The legs were sharply adducted and flexed with the knees against the chest. The heels were open to the os calci, and the ischial tuberosities were both exposed where the heels had kept constant pressure. The inner surfaces of the knees were bared, the patellas were exposed, and early erosion had begun on the chest, all from the constant spastic rubbing at these points. However, the most important decubiti were at the hips. Although the external appearance of these showed granulating areas no greater than 10 cm. in diameter, huge pockets were present in each. These pockets extended around the greater trochanters and led to huge osteomyelitic cavities representing almost total destruction of the acetabulum, head and neck of both femurs, with extension down both femoral shafts. A sacral decubitus extended as high as the second lumbar spinous process. At first appraisal, it seemed wisest to agree with the prognosis found in the patient's transfer records—death in a month or less. However, other experiences with patients in almost equally severe conditions led to consideration of anterior rhizotomy. He was given blood transfusions, and the decubiti were carefully dressed. Spinal anesthesia demonstrated the presence of far advanced contractures. Anterior rhizotomy was carried out without anesthesia other than that provided by the injury, and the patient was still alive at last examination, about two years later.

There is no need for patients to be allowed to deteriorate into this deplorable state. It can result only when there is insistence that flexor spasticity will wear out. Patients with complete lesions and disabling flexor spasticity should all be considered for early anterior rhizotomy. Certainly in civilian practice, this decision must be reached early in order to protect the financial status of the patient. As such, exploration of the site of injury assumes added importance, for proof of anatomic transection would hasten the decision to utilize anterior rhizotomy with the advent of disabling spasms. Without assurance that the transecting lesion is anatomic rather than physiologic, it is difficult to approve of a destructive procedure such as anterior rhizotomy. In the occasional patient, freeing of arachnoid adhesions will produce remarkable relief. Other procedures for relief of spasm, such as posterior rhizotomy, alcoholic injection of the spinal cord and continuous spinal anesthesia, are not generally regarded as successful enough to warrant use.[59] There is little usefulness for drugs in the treatment of flexor spasticity in patients with complete paraplegia. My experience is not in accord with the enthusiastic reports of others.[60] The amount of relief seen in incomplete paraplegia is in itself so limited that curare cannot be relied on to give much improvement. Furthermore, in a series of cases of complete paraplegia (more than 100) there was not 1 case in which relief worthy of mention was seen, despite the use of doses far greater than any advocated for patients who are not receiving artificial respiration. All patients were treated to levels of toxicity. The same can be said of neostigmine.[61] Quinine was briefly investigated and showed some promise. The depressant effect of the barbiturates is usually equal to anything demonstrable by other drugs. Despite the apparent lack of action of these drugs, it is hoped that the search will be continued for drugs which will depress spasmodic movements, without the deleterious side effects of neostigmine and curare.

Physical therapy was used constantly for the patient with spasms. In many, Hubbard tank baths proved to have a relaxing effect, but in some the relaxation was followed in several hours by severer bouts of spasm. Deep massage proved to have little usefulness, but light massage was more efficacious. Ambulation often reduced spasm in incomplete lesions; in some complete lesions this was also true, although in most the violence of the spasmodic movements was increased.

Of the seemingly more radical surgical procedure, such as excision of the scarred stump of cord,[62] it can be said only that further research is still needed. Any procedure which damages the cord severely will abolish spinal cord reflexes for about six weeks, a point which must be remembered in evaluation of any therapy.

## REHABILITATION

Rehabilitation is the principal means of reaching the ultimate goal whereby the paraplegic patient accomplishes a reorientation to his disabled state and enters society again as a useful citizen. There is little agreement as to the percentage of patients with paraplegia who can reach this goal. As stated by Munro[1c]:

> If he has been properly treated, every patient with a spinal cord or cauda equina injury who is intelligent and cooperative and has the use of the shoulder, arm and hand muscles can be made ambulatory; can have such control of the bladder and bowels as to sleep through the night without either getting up or wetting himself; can carry out ordinary activities throughout the day without soiling himself with feces or having to evacuate his bladder oftener than once every three hours; can lead a normal social life, and within the limits of his intellectual capacity, can earn a satisfactory living.

This attitude is taken by most heads of paraplegia services and by Covalt.[63] Many others have expressed the opinion that none could be rehabilitated. Is the optimism of Munro or the pessimism of his detractors representative of the greatest likelihood? It was estimated that approximately 2,500 soldiers suffered spinal cord injury and survived to be returned to the States during World War II. Of these, approximately 10 per cent had paralysis of all four limbs. This cuts the figure of the number who could use their hands to 2,250. The late death rate was low, in our series less than 3 per cent, thus cutting the number to about 2,175. In the present centers for the care of paraplegic patients, approximately 1,000 are still hospitalized. This puts over 50 per cent at home. A questionnaire sent to several hundred patients known to have been discharged indicated that the vast majority met the requirements for being designated as rehabilitated. Checking those who had not been rehabilitated against their data on intelligence and aptitude showed that many of them were deficient in these fields. Of those still in the hospital, many could leave if the factor of social security could be established. If a physician assumes that his job is ended with the healing of visible wounds, then rehabilitation will almost always fail. Rehabilitation must encompass every phase of human activity, or it will likewise fail. Thus, failures to date cannot be blamed on any deficiency in knowledge, but in the application of known methods. The simplest answer to the problem is to insure a hospital bed for each patient and to care for his immediate medical needs on a domiciliary basis, with the hope that the pathetic condition will not last too long. In the patient past middle age, it may well be that ambulation is impossible and that one must be content with care in bed. However, this is not true for the average younger patient or for many of the older ones in whom at least wheel chair ambulation is usually possible. Any failure to reach full rehabilitation in young intelligent patients should be blamed on the social order that permits medical apathy and ignorance of the possibilities. Even if the patient has intelligence of a low order—and an unfortunately high number of such are represented in the present group—there still exists the possibility of total rehabilitation. To convert this possibility into a reality, everything around the patient must be taken into account, and proper corrections made. For example, if a patient springs from a tenement area, he must have new surroundings, such as that provided by a beneficent community, as depicted in the pages of a popular magazine.[64] To insure continued health, he must be active. To maintain activity and to provide income, an occupation must be provided. The range of activity in the search for a fitting vocation is by no means limited. One patient recently wrote that he was awaiting the decision on an appeal to an order denying him a commercial airplane pilot's license. A skilled pilot (he had been in a plane only once before injury), he is keeping busy by doing radio repair work (also learned since his injury). Such cases are not exceptions. Others have set up watch repair shops, taverns and small newspapers. All in all, one cannot expect a man whose best efforts without injury would make him the second best shoe repairman in town to be tuned to the position of town mayor—but he can be made the second best shoe repairman. To reach the goals briefly discussed, the following pattern is given for guidance:

*a. Psychologic Rehabilitation.*—It is essential that the patient be told as soon as possible that he will never walk normally again and that he will have loss of voluntary control of his bowel, bladder and sexual function. If laminectomy has been done, the physician often is better able to prognosticate. The technic of placing new patients near others with severer lesions, especially if these patients have progressed with rehabilitation, deserves special emphasis. The patient must have supreme confidence in the doctor, for severe emotional trauma results from a disinterested physician's telling the patient of his prognosis or relying on the family to convey the bad news. At the same time that the prognosis for voluntary function is given, a careful outline of the possibilities in rehabilitation should be given. Without this opening approach, it is difficult to get the patient started on the course to rehabilitation. Psychiatric consultation is rarely advisable in the otherwise normal patient, for the patient has supreme confidence in two men—his personal physician and his surgeon, who should deal with the psychologic problem promptly and properly. Although the emotional trauma resulting from the revelation of the severity of the physical injury is great, it is important to get the full cooperation of the patient early. Honesty with the patient pays great dividends in cooperation. If it cannot be stated with positiveness that the prognosis is bad, then it should be stated that the assumption of its being bad carries with it the best approach. This is necessary to prevent delay in one's initiating rehabilitative procedures while awaiting hoped-for function that may never appear. It is essential that all aspects of the future be discussed. This includes the home situation, finances, ambitions and desires. Relatives must be interviewed. Needless to say, a complete medical and social history is essential. With the acceptance of disability and the determination to go through the necessary steps to return to society, the future course of the patient is almost assured. Psychic deterrents, such as tubes in the bladder, are removed promptly as previously indicated. In the discussion, it is assumed that the patient is receiving ideal care. As the predicted levels of attainment are reached, the emotional status of the patient will show distinct improvement, until all that is left is reflection on the absence of sexual ability. In this sphere lies the greatest single barrier still unsolved in the complete rehabilitation of the paraplegic patient. Female patients, especially if unaccustomed to orgasm, are more readily satisfied. In men, the lesions of the cauda equina leave an exasperating inability to consummate the sexual act. With lesions to the spinal cord, tricks may be found which induce priapism of a sufficient nature to allow completion of the physical portions of the act, with many deriving sufficient emotional satisfaction to act as a suitable balm.

*b. Physical Rehabilitation and Bracing.*—To care for himself completely, the paraplegic patient requires almost herculean shoulders and arms. In the first two weeks after injury, complete bed rest is advisable. Unless the anterior longitudinal ligaments of the vertebral bodies have been interrupted, extension can then be tolerated. The patient should be transferred to an exercise mat, preferably raised from the floor to ease the task of the therapist and instructors.[65] Flexion of the spine should be avoided during the period of bony healing. In general in cervical injuries, a Thomas collar or turnbuckle extension collar can be used instead of cranial traction after three weeks, although for many a Minerva jacket is best for periods up to four months. Some type of support is usually required for at least a year. For thoracic and lumbar injuries—without damage to the anterior longitudinal ligament—bracing in mild hyperextension is necessary until stability is evident. More care is required in patients with damage to the anterior longitudinal ligament and in those showing rapid recovery of function. Frequent roentgenographic check of the status of the bony alinement should be made. Obviously, if laminectomy has not been performed, initiation of activity must await evidence of bony healing. Push-ups, pull-ups in the prone position and gripping exercises should be instituted. With a graded exercise system such as that described by de Lorme,[66] it is possible to have almost every patient capable of supporting his weight with one arm in a period of six weeks. During this time, the patient is allowed in a wheel chair, provided that adequate bracing of the bony lesion is obtained. As soon as bony healing is demonstrated (and before in the patient with a proved anatomic transection), weight bearing should be allowed (fig. 5). This should be anticipated by enough time to allow measurement, manufacture and fitting of braces. For patients with ability to lock the knees, only drop foot braces should be used. For those unable to lock the knees, long leg calipers are needed. For patients with lesions above the tenth dorsal dermatome (best described as those unable to "hike" the hips), a pelvic extension brace may be needed. The subject of braces has engendered some bitter controversy.[67] Perhaps the most important point was missed. If the patient is required to support over 100 pounds (45 Kg.) of dead weight body, the addition of about 15 pounds (7 Kg.) of bracing "adds the straw that breaks the camel's back" and the patient soon abandons the trying effort. However, if the braces are light yet durable, he will put them to good use. To attain this goal, strapping should be minimal. A strap over the knee cap with another surrounding the upper leg is most usually adequate. A drop foot attachment is needed as is a good, easily workable knee lock. The best all-round brace available is the Klenzak brace, the parts of which, assembly apparatus and instructions are supplied by the Pope Foundation.[68] By keeping strapping down to a minimum and by making the brace easy to apply, one virtually insures continued use. If it requires help and much time to apply a brace, it will soon find its way to a corner to gather dust. Crutches should be sturdy and should be carefully measured for the individual patient. Sponge arm rests should be frowned on, since the crutches should not be used to support the body weight in the axillas. The crutch tips should be of suction type.

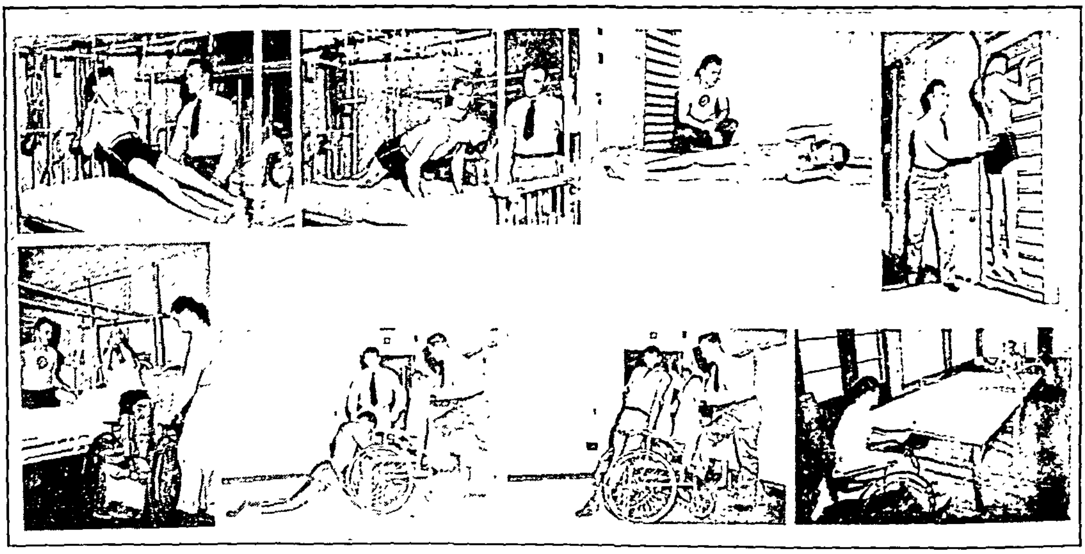

Fig. 5.—Phases in physical reconditioning of paraplegic patients (from Dr. J. C. White and Dr. T. I. Hoen).

*c. Ambulation.*—With the patient having reached the stage where weight can be borne on the extremities, the erect posture should be assumed between parallel bars. The bars should be adjusted to the level of the hand grips on the crutches. Here the patient learns balance and launches on the preliminary crutch-walking gaits of swing-to (feet dragged to standing position from a bent forward initial position) and swing-through (feet thrown ahead of vertical line of body by a pendular motion). With full length mirrors at each end of the walking ramp, the patient is taught balance without requiring direct observation of the position of his feet. During this period he begins balance exercises with crutches, learning to throw the crutches forward and backward, and to shift the position of the crutches and body from side to side. He then begins forward motion with the crutches, with men stationed before and behind to prevent his falling. The swing-to gait is first mastered and then the swing-through. These gaits are often sufficient for most patients with lesions above the tenth dorsal segment and may be the only ones which they can do (fig. 6). If the patient is able to "hike" his hips, he then starts with alternating gaits. From this point on, the development of ambulation is an individual matter. Few patients with lesions above the tenth dorsal segment will be able to put ambulation to good use in moving further than from room to room, but it must be reemphasized that the real purpose of ambulation is the prevention of urinary calculous formation and without it the patient has a limited life expectancy. It must be done daily for a minimum of one-half hour for the medical benefits alone. Some of these patients can accomplish navigation of stairs and curbs, thus having a good, useful means of loco-

motion. For those patients with lesions below the tenth dorsal segment, all expected obstacles are simulated and special attention given to each (such as street curbs). A useful guide for achievement is "What's My Score," put out by the Veterans Administration.[69] Attention must be given to the different types of surfaces to be met, and the patient must be taught how to get up from the ground alone. In line with this, he should be taught how to get in and out of a car alone, usually from a wheel chair. By using a light-weight folding wheel chair, the patient can accomplish this alone. He should be given careful driving instructions in a specially equipped automobile. In all phases of daily care, he must reach proficiency in full accomplishment without aid. If he is dependent on outside aid for anything, his activity is likely to be too restricted. Emphasis is placed on full self care.

*d. Educational Reconditioning.*—For some to attain the best possible vocation, further education is needed. Regardless of any other consideration, it is necessary that the vocation chosen be capable of achievement and be completely fitted to the patient's needs and abilities. As such, a full range of intelligence and aptitude tests should be given. With this information, it is possible to narrow the field of possible vocations. Having selected the proper one, one must remove all educational deficiencies. Many paraplegic persons are now in attendance at some of the country's leading colleges.

*e. Vocational Rehabilitation.*—As a continuation of the testing of aptitudes and selection of a vocation, the total range of vocational training must be assured. This includes ultimate placement. That such a goal is attainable is exemplified by the patients already mentioned and more so by the watch repair training offered by the Veterans Administration, which includes a year at the school of one of the leading watch companies. Again, the vocation must be fitted to the patient, not the patient to the vocation. These patients can then conduct themselves more favorably than those who entered their vocations by pure chance, without being properly fitted.

*f. Social Rehabilitation.*—This encompasses all phases of activity, but the major part of this will be automatic once bowel and bladder control are assured. However, communities must receive instruction in their duty to and attitude toward paraplegia. This largely consists of acceptance of the patient as a normal member, and not as some sort of pitiable freak. Active support may be required, but should not be done as a purely charitable venture. Since the expense of the entire program is so great, it is probable that only a government-financed center, open to veterans and civilians alike, can fulfil all requirements. Such a center would fail unless it had sympathetic support and was staffed by men with genuine interest.

### THE CIVILIAN PARAPLEGIC PATIENT

Repeated reference has been made to veterans and to the hospital facilities of the Veterans Administration. This is natural, as my principal experience has been with veterans of World War II in Army and Veterans Administration hospitals. Furthermore, present concepts of the proper treatment of the traumatic paraplegic patient and of his potentialities have been largely the result of experiences resulting from that war. However, I wish to avoid creating the impression that the problem of the care and rehabilitation of the paraplegic patient is exclusively or even predominantly one concerned with veterans. Nothing could be farther from the truth. Traumatic paraplegia, as well as paralysis of the legs resulting from other diseases of the spinal cord, such as myelitis, multiple sclerosis and tumors, is an enormous and ever present problem among civilians. Such injuries are all too frequent in mines, on farms and in factories. Although we now know how to treat patients who have been so injured, as has been outlined in the preceding pages, the facilities for such treatment are lacking for all except the veterans of World War I or II. No civilian hospital has either the equipment or the personnel to provide the treatment which these persons require, and few civilians could afford the months and years of such treatment which their condition requires even if it were available. It

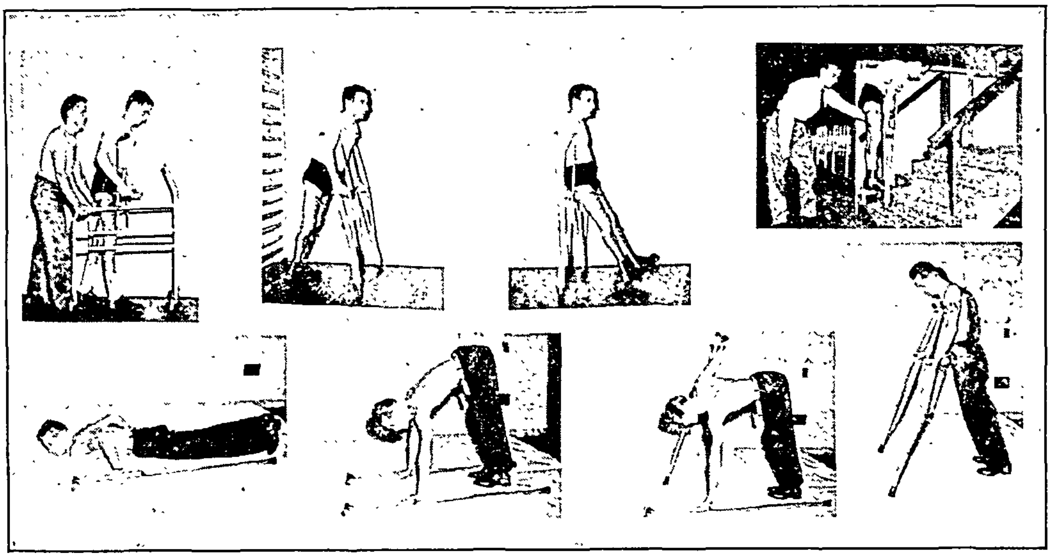

Fig. 6.—Some phases in ambulation of paraplegic patients (from Dr. J. C. White and Dr. T. I. Hoen).

---

69. Veterans Administration, Central Office, Washington 25, D. C.

is important for the education, rehabilitation and maintenance of the proper morale of the paraplegic patient and for the maintenance and training of a proper attending staff of physicians, nurses and orderlies that the patients suffering from paraplegia be cared for in large groups in centralized hospitals scattered at strategic points throughout the United States. The expense of the care of such patients is so great that such hospitals cannot possibly be supported entirely by the patients themselves. The support of such institutions should be the joint concern of the patients, casualty insurance companies, industry, labor unions and the government. A beginning in the proper development of such centers has already been made by the Veterans Administration. These facilities could well be expanded to care for the civilian patient and financed by the interested parties previously designated. This is not a visionary plan incapable of prompt attainment. In fact, our good neighbor to the north, The Dominion of Canada, has, through the hospitals under the control of its Department of Veterans Affairs in collaboration with its university medical schools, already shown the way by establishing exactly the type of facilities outlined here. This program is already in full and successful operation there. There is no longer adequate justification of the failure of development of facilities for the care of the unfortunate civilians here.

It is to the great credit of our paraplegic veterans that they have taken the lead in the establishment of adequate care for the civilian paraplegic person who has not had the advantages that the hospitals of the Army, Navy and Veterans Administration have provided them. They are acutely aware of the handicaps, pains and discomforts associated with paraplegia; they know at first hand the intensive, persistent and expensive care which is essential if the paraplegic person is to live, be comfortable and to be rehabilitated to a socially and economically useful life; they know that without such care most paraplegic persons are condemned to death within a few months. To the end that this deficiency in the care of all paraplegic patients may be improved and advanced by study and research, the paraplegic veterans have organized The National Paraplegia Foundation. Its works and aims should be aided whenever and wherever possible.

### SUMMARY

A system of care of patients with injury to the spinal cord, based on personal observation on more than 720 cases is given. To this is added the judgment of outstanding civilian and military authorities with wide experience. The system is presented with the hope that many of the features which came to light during the last war will be put to use in civilian practice.

Emphasis is placed on the following features: (*a*) immediate first aid care of the patient, (*b*) reduction of the deformity of the spine, (*c*) frequent rotation of the patient to prevent decubitus ulcers, (*d*) prompt bladder treatment, (*e*) attention to protein balance, (*f*) care of the bowels and (*g*) psychologic aspects. Details are given for bladder care, bowel care, nutrition, psychologic aspects and ambulation.

Ambulation is stressed for its general health value and as the only certain means for prevention of urinary tract calcinosis. Rehabilitation is discussed as a means of reaching the ultimate goal, whereby the paraplegic patient accomplishes a reorientation to his disabled state and enters society again as a useful citizen.

## Clinical Notes, Suggestions and New Instruments

### A FATAL REACTION TO METHAPYRILENE (THENYLENE®)

HUGH F. RIVES, M.D.
BERL B. WARD, M.D.
and
M. L. HICKS, M.D.
Dubuque, Iowa

Methapyrilene hydrochloride is N,N-dimethyl-N'-(2-pyridyl)-N'-(2-thenyl) ethylenediamine hydrochloride (thenylene hydrochloride®, Abbott) and is an antihistaminic drug.

Since the antihistaminic drugs have become available to the members of the medical profession, both the lay press and many physicians have hailed these preparations as practically nontoxic and as the solution to most allergic problems. That present indiscriminate use of these antihistaminic agents needs a critical review is evidenced in the literature. Although we have found no report of a fatality, there have been serious reactions.

Roth and co-workers[1] from the Abbott Laboratories reported the pharmacologic properties of methapyrilene. On isolated portions of ileum in the guinea pig and rabbits, they demonstrated that this drug definitely prevented or abolished the spasm-producing activity of histamine. They also demonstrated its inhibitory action on anaphalaxis in the serum-sensitized guinea pig. The authors, in discussing acute toxicity in experimental animals, noted excitation followed by convulsions. In cats and dogs the respiratory acceleration was prominent. The course of events may be rapid or slow; depression may precede death, or death may result from respiratory arrest and convulsions.

Roth and associates[1] did not discuss any pathologic studies on the experimental animals which were killed by acute toxicity but did mention that, in a group of animals which received methapyrilene over a long period (eight months), pathologic studies revealed that the heart, kidneys, spleen, adrenal glands and digestive tract were essentially normal. The liver exhibited decided cloudy swelling.

Logan[2] stated that, in a series of 71 children who were treated for certain allergic diseases with diphenhydramine (benadryl®), undesirable side reactions occurred in 17, or an incidence of approximately 24 per cent. The reactions were chiefly drowsiness, vomiting, diarrhea, headaches and, in the case of one boy 3 years of age, who took 320 mg. of diphenhydramine hydrochloride over a period of three days, gross hematuria.

Horton[3] stated that Logan had recently seen a patient with an acute reaction to methapyrilene characterized by excitation and convulsions. Prompt gastric lavage was performed, and he believed that this procedure was largely responsible for the child's recovery.

Kierland and Potter,[4] in reviewing their experience with this drug, noted untoward reactions in 21 of 78 cases, or an incidence of approximately 27 per cent. The reactions consisted chiefly of drowsiness, dizziness, nausea, vomiting, headache and nervousness. The authors stated that serious toxic reactions had not occurred but that it was necessary to discontinue treatment in several cases.

Sternberg[5] observed side reactions in about 65 per cent of his cases. He reported in detail the history of a student nurse aged 22 in whom hysteria developed while she was taking diphenhydramine for hay fever. On withdrawal of the drug the hysterical episodes ceased, and she became normal and returned to work.

[4] Kierland, R. R., and Potter, R. T.: An Evaluation of Thenylene, Proc. Staff Meet., Mayo Clin. **23:** 48-51 (Jan. 21) 1948.

[5] Sternberg, L.: Unusual Side Reaction of Hysteria from Benadryl, J. Allergy **18:** 417 (Nov.) 1947.

Lott, Krug and Glenn[6] also noted an acute psychosis in the case of a woman aged 20 who was given tripelennamine (pyribenzamine®) orally to control a dermatitis due to either sulfadiazine or penicillin. The dose of tripelennamine hydrochloride was 100 mg. every four hours. The woman rapidly returned to normal after discontinuation of the drug.

Kern[7] reported that a woman aged 28 suffered fainting spells and severe prostration after taking 300 mg. of tripelennamine hydrochloride in equally divided doses, approximately eight hours apart.

In a recent article Sachs[8] reported a toxic reaction in a white man 28 years of age who was treated with 600 mg. of diphenhydramine hydrochloride daily for severe urticaria caused by penicillin. After two and one-half days there developed dizziness, dryness of the mouth, visual and olfactory hallucinations, mental confusion, tremor and jerky speech. Complete recovery of the patient occurred twelve hours after the discontinuation of the drug. The author reviewed the literature and stated that: (1) toxic reactions with therapeutic doses of the drug occur in 46.4 per cent of cases; (2) when diphenhydramine is given intravenously, toxic reactions occur in 65 per cent of cases; (3) the drug was discontinued in 6.4 per cent of cases because of toxicity; (4) toxic reactions are unpredictable because they may occur even with small doses on some occasions and not on others in the same case (reactions were more frequent, however, with higher dosages), and (5) toxic reactions are relieved by discontinuation of the drug. No cumulative effect was noted.

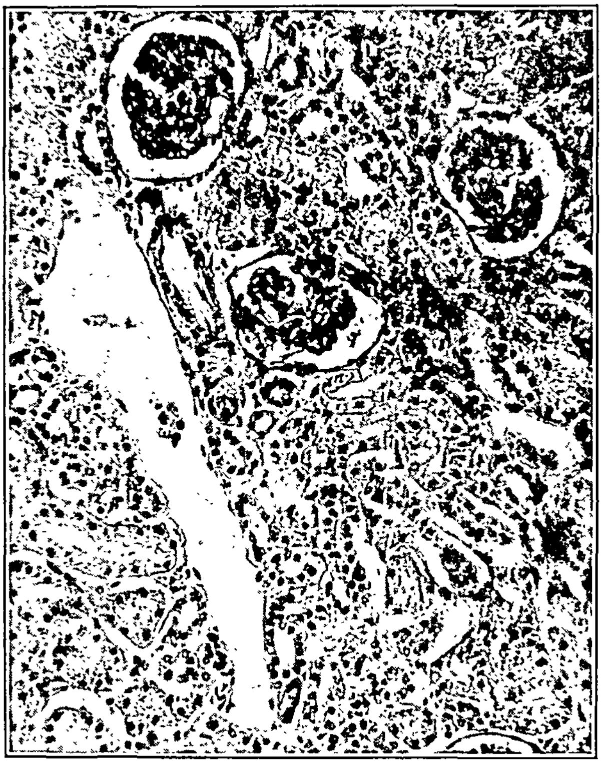
## REPORT OF CASE

We have recently seen a fatal reaction to methapyrilene.

*History and Clinical Course.*—The patient, a white girl aged 16 months, had been in good health prior to the present illness. Birth had been by normal spontaneous delivery. There was no history of serious illness during infancy or evidence of congenital abnormalities. Her physical and mental development was normal. At the time of the present illness, the patient's weight was 24 pounds (10.9 Kg.).

On March 28, 1949 the child accidentally ingested 100 mg. of methapyrilene hydrochloride at 9:30 a. m. At 11:30 a. m. there was projectile vomiting, followed by listlessness and a desire to remain quiet. Approximately 4 ounces (118 cc.) of milk were drunk without further vomiting. There followed occasional tetanic jerking of the extremities, climaxed by a severe clonic convulsion at 1:10 p. m. This lasted two to three minutes and was followed by a short period of consciousness. This was succeeded in four to five minutes by a continuous clonic convulsion. The patient was admitted to the emergency room of St. Joseph Mercy Hospital, where the convulsions were controlled by the inhalation of ether and oxygen. One grain of pentobarbital sodium was given intramuscularly. At the time of admission the pupils were widely dilated and there were extremely irregular movements of the eyes. Some muscular twitching of the arms and face persisted. The general condition was good, and 7.5 grains of chloral hydrate were given rectally. The pulse rate at this time was 92 per minute, and the respirations numbered 50 per minute. The subcutaneous administration of a 5 per cent solution of dextrose in water was begun. At 5 p. m. muscular twitching of the arms returned and breathing became more rapid and labored. There was a small amount of coffee-ground vomitus. The temperature was 105 F. (rectal). Seven and one-half grains of chloral hydrate were again given per rectum. The patient's temperature gradually rose to 107 F. (rectal), and there was a gradual increase in respiratory rate and some slowing of the pulse rate. Muscular twitching of the arms increased. A venesection was performed at 7:30 p. m., and an intravenous infusion of a 5 per cent solution of dextrose in water was begun. At this time the carbon dioxide combining power of the blood was 25 mg. per hundred cubic centimeters and the nonprotein nitrogen was 240 mg. per hundred cubic centimeters. Observations of the blood were otherwise essentially normal. One-sixth molar lactate solution was substituted for the dextrose to correct the acidosis. The patient had not voided since admission to the hospital. By catheterization only 20 cc. of urine were obtained. The urine was acid and gave a 2 plus reaction for albumin; there was no sugar or acetone; there were 1 to 2 white blood cells, 15 to 20 granular casts and 2 to 4 hyaline casts per high power field. The patient's condition remained static with the temperature varying from 105 to 107 F. (rectal), the pulse rate, from 90 to 100 per minute, and the respiratory rate, 40 per minute. At midnight respirations gradually increased to 50 per minute, and the pulse rate suddenly slowed to 50 per minute. The rectal temperature was 107.2 F. The pulse rate continued to slow, and the heart beat and respirations suddenly ceased at 12:40 a. m., approximately fifteen hours after ingestion of the methapyrilene.

*Necropsy Data.*—The necropsy was performed by Dr. E. T. Thorsness. The body was that of a well nourished white girl of 16 months. There were no evident physical abnormalities or congenital defects. The principal abnormalities were decided cortical edema of the brain and upper nephron nephrosis. (See the accompanying illustration.) The kidney section revealed degeneration and fragmentation of the cells of the proximal convoluted tubules. The glomerular spaces were increased in size as a result of obstruction in the proximal convoluted tubules. In addition, there were some cloudy swelling of the pancreas and liver, splenic congestion and edema of the lungs, with intra-alveolar hemorrhage. The diagnosis was acute poisoning due to methapyrilene.



Destructive lesions of glomeruli and proximal convoluted tubules of kidney (× 170).

## SUMMARY

The fatal poisoning of a healthy girl 16 months of age was caused by the accidental ingestion of 100 mg. of methapyrilene hydrochloride (thenylene hydrochloride®, Abbott). The principal features were nausea, vomiting and drowsiness, followed rapidly by excitation, tremors, convulsions and death. The principal abnormalities at autopsy were cerebral edema and what we term upper nephron nephrosis, with immediate anuria and tremendous rise of the nonprotein nitrogen.

[7] Kern, E. C.: Marked Toxic Side Effects of Pyribenzamine, J. M. Soc. New Jersey 44: 374 (Sept.) 1947.

[8] Sachs, B. A.: The Toxicity of Benadryl: Report of a Case and Review of the Literature, Ann. Int. Med. 29: 135 (July) 1948.

### CONCLUSIONS

1. A brief review of the literature indicates that toxic reactions occur with the therapeutic use of antihistaminic drugs in from 25 to 65 per cent of cases.
2. The altered physiology which produces these reactions is unknown.
3. Most of the reactions seem to be a result of cerebral irritation.
4. More observations should be made on the cerebral and renal lesions of animals which have been killed by a toxic dose of antihistaminic drugs.
5. There is no effective antidote for these drugs. The only treatment is withdrawal of the drug and symptomatic support of the patient.

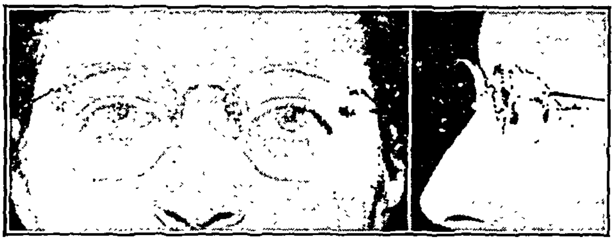
1200 Main Street.

## A MIRROR FOR PATIENTS WITH HEMIANOPSIA

ERIC BELL Jr., M.D.
Cleveland

Hemianopsia is relatively frequent among patients with intracranial lesions. Most of these defects are of the nature of a homonomous hemianopsia. Patients with this disability often complain of the repeated dangers and embarrassments which occur as the direct result of their restricted field of vision. They fail to see swiftly moving automobiles, they are afraid to gaze into shop windows because of the probability of colliding with other pedestrians and they fail to see the food passed to them at the dinner table. The complaint is usually worded thus: "If I only knew that something were approaching me on my blind side, I could turn my head and look over there—but I don't know when to look."

In an effort to find some gadget which would aid these patients in "knowing when to look," a simple device, consisting only of a small, oval mirror measuring about 1 by 2 cm., was affixed to the nasal portion of the inner aspect of the patient's glasses.[1] The size of the mirror must necessarily depend on the height of the patient's nasal bridge. A slightly convex surface to the mirror may be desirable. The best angle is approximately a right angle to the plane of the lens of the glasses. It should be attached to the metal frame near the nosepiece (see illustration).



Frontal and lateral views of glasses with mirror attached. Note the reflection of the pupil in the mirror.

Patients seem pleased with the resultant increase in their field of vision. When some movement occurs on their hemianoptic side, they often are able to catch a glimpse of this in the mirror and thus are prompted to turn their eyes in that direction. The position of the mirror has the added advantage that the farther a patient turns his eyes to his "good" side, the clearer and wider the reflection he sees from his hemianoptic segment of vision. Patients rapidly learn to interpret the glimpse with fair accuracy, so that material benefit may occur within a few weeks. Failure to attain benefit may indicate that the angle of the mirror should be changed. Variations of this basic device may be used for patients with other types of visual field defects.

## PRESENT STATUS OF ALUMINUM IN THE THERAPY AND PROPHYLAXIS OF SILICOSIS

ERNEST W. BROWN, M.D.
Executive Officer to the Committee on Scientific Development and Education, Council on Industrial Health, American Medical Association
and
WALTON VAN WINKLE Jr., M.D.
Secretary, Therapeutic Trials Committee, Council on Pharmacy and Chemistry, American Medical Association

A conference of representatives of the Council on Industrial Health of the American Medical Association and of the McIntyre Research Foundation was held at Toronto, May 10, 1946, to exchange views between the two agencies regarding future activities of the McIntyre Research Foundation in the United States. The following program was formulated:

1. That the Councils on Industrial Health and on Pharmacy and Chemistry of the American Medical Association continue to evaluate all data available on the toxicology of aluminum.
2. That a conference be called between the two councils concerned and the McIntyre Research Foundation to discuss further the current status of the efficacy of aluminum in relation to the therapy and prophylaxis in silicosis and the licensing procedure now in operation.
3. That, if possible, a report be obtained on the experience gained in the aluminum treatment of miners at Timmons, Ontario.
4. That a complete report of the study of Dr. D. W. Crombie on the treatment of cases of tuberculosilicosis with aluminum be made available.

The conference proposed was held at the headquarters of the American Medical Association Oct. 31, 1946. This included representatives from industry where the aluminum procedure was in use, members of the two Councils, the Therapeutic Trials Committee and officials of the McIntyre Research Foundation. The consensus was that the licensing procedure entailed certain objections which were outweighed by other advantages, provided that licensing was not demanded of research personnel. Representatives of the two Councils agreed to undertake an inspection of a representative group of industrial installations for aluminum prophylaxis and therapy in the United States, as a means of reaching a more comprehensive conception of how the procedure was being applied and of determining whether any significant data for evaluation were available.

Definitions: The term, aluminum, as related to prophylaxis and therapy in this report signifies the finely divided preparation adopted by the McIntyre Research Foundation.[1] It consists of approximately 20 per cent metallic aluminum and 80 per cent aluminum oxide. Each particle is made up of a core of the metal surrounded by the oxide, 99 per cent of the particles being under 5 microns in diameter. Alumina is another term for aluminum oxide, which may exist in the amorphous or crystalline form. The white amorphous powdered material selected by Gardner, Dworski and Delahant[2] as the antidotal agent against silica dust is designated "alumina XH-1010." This is the dried state of a precipitated gelatinous form of aluminum hydroxide.

## PREVIOUS SURVEYS ON THE STATUS OF ALUMINUM THERAPY

Tabershaw and Tebbens[3] published a report in 1945 based on personal interviews and observation in various centers of the United States where aluminum was in use either as a prophylactic or therapeutic agent or both.

George[4] of Australia published an exhaustive report in 1946 of a visit to installations in Canada and the United States together with a general review of the subject.

King and Sutherland[5] of the Postgraduate Medical School, University of London, carried out conferences and inspections of the principal centers in the United States and Canada employing the aluminum process. This was conducted on the request of the Medical Research Council of Great Britain. They submitted a detailed but unpublished account of their observations at that time.

Dr. Lucien Brull[6] of the Institute of Hygiene of Mines of Belgium submitted to the institute in 1946 a report containing the results of his study regarding aluminum prophylaxis and therapy following a tour of industrial and other centers in the United States and Canada.

Dr. G. E. Hall,[7] formerly dean of the School of Medicine and now president of the University of Western Ontario, prepared an unpublished résumé in 1947 of the situation in Canada at the request of the Ontario Provincial Government. It contains a recommendation that a comprehensive independent study of the whole problem be undertaken by a government research organization.

Dr. A. R. Riddell,[8] of the Silicosis Referee Board of the Workmen's Compensation Board of Ontario, published in 1948 a paper in which he summarized the reports of various persons and groups who had visited certain of the numerous plants where aluminum therapy and prophylaxis are employed. Dr. Riddell is in general accord with the comments of these observers.

A review of these reports reveals general agreement with respect to the following points:

*Therapy.*—(1) A large proportion of silicotic patients who receive aluminum treatment claim total relief from subjective symptoms; (2) no convincing objective evidence of improvement either from clinical or radiologic records has been observed; (3) no adequate comparative control groups without treatment or with different treatment have been studied.

*Prophylaxis.*—(1) The results of confirmed laboratory animal experiments were so striking that application to man should also have been studied under scientifically controlled conditions; (2) mass prophylaxis should not have been introduced unless based on such experimental studies; (3) where aluminum has been administered for a considerable time to workers with previous prolonged exposure, there is no clear evidence that it will prevent progression; (4) it is too early for a conclusion as to whether administration of aluminum will prevent silicosis in persons receiving it from the beginning of exposure.

## POSSIBILITY OF ADVERSE EFFECTS OF ALUMINUM IN MAN

1. *Adverse Effects on the Normal Lung.*—Mass administration of aluminum has been in progress in the mines of Ontario for five to six years, involving many thousands of workers; also, in the majority of mines of British Columbia for roughly three years. It was begun in the United States in 1942, and there are now approximately fifty-five licensees employing the method. Nothing has appeared up to this time either in the literature or from any other source indicating that adverse effects have resulted from any of these applications.

No mention of harmful action is contained in the therapeutic studies of aluminum in silicosis of Crombie, Blaisdell and MacPherson,[9] Bamberger,[10] Wright,[11] Hannon,[12] Vrooman[13] and Berry.[14]

The Industrial Pulmonary Disease Committee of the Medical Research Council of Great Britain[15] in 1936 investigated both clinically and roentgenologically a group of 50 workers who had been exposed for a considerable period of years to the inhalation of alumina dust in high concentration in the reduction factory of the British Aluminum Company. No evidence of fibrosis of the lung or other pathologic effect was found as a result of this exposure. Attention is also invited to the fact[16] that for the past several years alumina has been substituted for quartz in the manufacture of china in British potteries. A relatively large number of employees have been exposed to the inhalation of considerable powdered alumina in this process, but no adverse physiologic effects appear to have been reported.

Crombie, Blaisdell and MacPherson[9] conducted a study of the records concerning the health of a group of 125 employees of the Aluminum Company of America who had been exposed to finely powdered aluminum for six to twenty-three years. No roentgen ray shadows attributable to aluminum or other evidence of injury was found in any case. Hunter and his associates[17] reported on a clinical and roentgenologic study of 92 duraluminum grinders in an aircraft factory who had been in an environment of alumina dust for one to fifteen years. There was no evidence that any disease of the trachea, bronchi or lungs had resulted.

Reports have appeared in the German literature by Goralewski and Jaeger,[18] Goralewski[19] and other investigators dealing with the examination of considerable numbers of workers who were exposed to aluminum dust in German war industries in World War II. Certain roentgenologic pulmonary changes and symptoms are reported, the pathologic picture being described as the "aluminum lung." The atmospheric concentration of aluminum was enormously high and the general environmental conditions very unfavorable in these plants. However, the evidence is not as yet convincing that aluminum was implicated. Follow-up studies[20] on these cases and the associated problem by British investigators have been in progress, but the findings are not yet available.

Whether or not alumina is a causative factor in Shaver's disease[21] is at present under investigation. The environmental conditions involve potential exposure to both alumina and silica fume, the alumina being dispersed in extremely small particles. The conditions are quite dissimilar to those prevailing in the therapeutic administration of aluminum. Decisive proof has not yet been obtained as to the exposure factor responsible for the disease.

The conclusion is justified that the administration of aluminum in the amounts used for therapy and prophylaxis is not harmful to the normal or the silicotic lung in the absence of tuberculous infection.

*Tuberculous Infection.*—Gardner, Dworski and Delahant[2] reported first that guinea pigs infected by inhalation of attenuated tubercle bacilli and exposed to heavy dosages of alumina displayed a transitory tendency toward the spread of the tuberculous foci but that later healing occurred without destruction of tissue. We are authorized by Dr. A. J. Vorwald,[22] Director of the Saranac Laboratory, to present the following unpublished data: Additional animal inhalation experiments have demonstrated that exposure to high concentrations of alumina for eight hours daily unfavorably influences resistance to tuberculosis, but subsequent studies, limiting treatment by inhalation to one-half hour daily, indicate that the alumina did not accelerate the course of a simultaneously developing benign experimental tuberculous infection.

However, in a similar experiment with aluminum for one-half hour daily, the tuberculosis showed a tendency to spread. Therefore there appears to be a difference between aluminum and alumina in that the former tends to stimulate the development of tuberculosis in the experimental animal while the latter does not have this action.

These observations lead to the question: Is there any specific evidence at present that inhalation of aluminum by man will activate a latent tuberculous lesion or exacerbate an active tuberculous infection? In view of this possibility, the McIntyre Research Foundation has stipulated from the beginning, both in Canada and the United States, that tuberculosis be ruled out in the case of all workers before commencing treatment with aluminum, whether prophylactic or therapeutic. Crombie[20] of the Queen Alexandra Sanatorium, Ontario, treated eight silicotic patients with the definite complication of tuberculosis, the patients inhaling aluminum for fifteen minutes every other day for two months. The inhaled concentration corresponded to that prescribed in the therapeutic study of Crombie, Blaisdell and MacPherson.[9] Crombie is of the opinion that no effect—favorable or unfavorable—on the tuberculous infection resulted. The number of cases in this series is statistically too small to justify a definite conclusion.

We are not aware of any other concrete data on this debatable point. However, the following comment from Dr. W. D. Robson,[23] chief medical director of the McIntyre Research Foundation of Canada, is pertinent: ". . . it is my confirmed opinion, which agrees with Dr. Crombie, that our aluminum powder in the amounts used for both types of treatment has no effect one way or the other on this condition. This information is based on personal interviews with various examining doctors throughout Canada over the period of the last four years." Information has also been received from Dr. J. W. G. Hannon,[24] medical director of the foundation in this country, that no reports have come to his attention indicating an adverse influence on tuberculosis of treatment with aluminum.

If the results of experimental animal studies were applicable to man, the use of alumina would not unfavorably influence early tuberculosis but use of aluminum might be contraindicated. At present the possibility of detrimental action is not supported by statistical evidence and therefore is neither proved nor disproved. However, nothing has developed which would alter our position that great care should be taken to exclude tuberculosis in selecting persons to receive treatment with aluminum.

## PRESENT STATUS OF ALUMINUM THERAPY IN SILICOSIS

Groups of patients have been treated by Crombie, Blaisdell and MacPherson,[9] Bamberger,[10] Wright,[11] Hannon,[12] Robson,[25] Vrooman[13] and Berry.[14] Unless otherwise specified, aluminum was administered by these various observers. Crombie and associates reported clinical improvement in 55 per cent of 34 cases. Hannon found relief of subjective symptoms in 94 per cent of those with disability and 89 per cent without disability. Bamberger reported subjective improvement in 49 per cent of his patients, 11 being given aluminum and 24 alumina. Wright recorded that 35 per cent of his 36 subjects claimed amelioration of symptoms, part receiving aluminum and the remainder alumina. Robson in 1943 and 1944 tested a group of 39 underground miners and 14 surface men and reported relief in 68 per cent of the total of such symptoms as dyspnea, cough, pain and tightness in the chest. Vrooman carried 23 patients through a complete course of treatment and noted that 57 per cent claimed betterment of condition.

The recent study of Berry merits special emphasis in this review. Prior to his work the appraisal of aluminum as a therapeutic agent had been complicated by the concurrent lack of adequate control groups of men to whom a placebo was administered in the form of air free from aluminum by means of the same technic as applied to the test groups. Berry's treated group consisted of 26 persons with silicosis. "Alumina XH-1010" was employed, the men receiving on the average a total of one hundred and thirty treatments, extended over a period of one year. The concentration of alumina was 300,000,000 particles per cubic foot, and the particles averaged 1 to 3 microns in diameter. The control group was made up of 16 persons with silicosis who were administered air free from alumina but were under the impression throughout that they were under treatment identical with that of the test subjects. Subjective improvement was claimed by 85 per cent of the treated group and by 100 per cent of the control group. Berry points out that while final conclusions cannot be reached from a comparative study of such a small series, it does stress that this type of control study is of the greatest importance.

The question naturally follows: Has convincing evidence of objective improvement been revealed along with the subjective relief of symptoms, such as significant gain in pulmonary function and regression of roentgen ray findings? Crombie, Blaisdell and MacPherson[9] reported that improvement in respiratory function was shown by one third of their treated patients. Wright[11] found that only 5 per cent of his group of 36 treated patients showed eventual benefit based on increase in pulmonary capacity. In both of these studies, the numbers involved were too limited to be of statistical significance.

We are not aware of any report of regressive change in roentgenologic classification resulting from the aluminum treatment of silicotic persons with the exception of 2 observed by Vrooman.[13] In one instance, nodulation largely disappeared in the roentgenogram; in the other, the change was complete. These effects are apparently not due to altered roentgenologic technic. On the other hand, progression has been found subsequent to therapy; this is discussed later in this report. There is no rational basis on which regression of the mature hyaline silicotic nodule could be postulated as a result of treatment with aluminum. It has not been demonstrated in laboratory animals.[22]

The present consensus is that the relief of subjective symptoms and better morale observed in silicotic persons following aluminum therapy are of psychologic origin and not the result of any favorable organic changes. We have heard the opinion expressed that the treatment, even if the effects are purely psychologic, would be justified on the basis of the promise of improved morale, restored working efficiency and better industrial relations. This entails the question how long the relief of symptoms persists after a course of treatment. Specific data concerning this aspect have not come to our attention.

### PRESENT STATUS OF ALUMINUM IN THE PROPHYLAXIS OF SILICOSIS

Aluminum prophylaxis will be considered from two standpoints; i. e., (1) prevention of silicosis in man free from roentgenologic evidence of the disease at the time when the procedure was begun and (2) prevention of progression as demonstrated by the roentgen ray when present at the start of aluminum administration.

*Fundamental Laboratory Animal Studies.*—Silicosis acquired new interest with the announcements by Denny, Robson and Irwin,[26] in 1937 and 1939, that it could be prevented by the inhalation of powdered aluminum. Gardner, Dworski and Delahant[2] reported in 1944 that alumina when inhaled would also inhibit the toxic action of silica dust on the lungs. The following statement is quoted from this paper: "As far as animals go, it may be said that confirmed experimental evidence proves beyond question that both aluminum and alumina specifically inhibit the toxic action of quartz, and that their administration will prevent progression of silicotic lesions and cause regression of immature lesions."

Subsequent unpublished research at the Saranac Laboratory[22] has led to the following conclusions, partly confirmatory and partly new:

(*a*) In animals inhaling alumina for one-half hour daily and then exposed to a high concentration of silica of 700,000,000 particles per cubic foot for seven and one-half hours daily, there is definite evidence of inhibition of the toxic action of quartz, but the protection is not absolutely complete, as microscopic cellular nodules occur in the lungs, some with necrosis and a few with early fibrous change. Comparable experiments with aluminum also show protection against quartz, but it is significantly not as effective as with alumina.

(b) In animals exposed to free crystalline silica, treatment with aluminum may cause retrogression of the early immature inflammatory lesion, provided the agent comes in contact with the silica prior to the advent of fibrosis. It has no effect on the mature hyaline silicotic nodule.

*Aluminum Prophylaxis in Man.*—On the basis of the animal studies of Denny, Robson and Irwin,[26] McIntyre Research Limited (now the McIntyre Research Foundation) was organized in Canada in 1939 with the object of controlling by patent the use of aluminum in the therapy and prophylaxis of silicosis in all countries. Mass administration was begun in the mines of Ontario in 1943, conducted in the change houses, so that virtually all workers are included. On the other hand, the aluminum powder is dispersed in individual treatment mills in the United States and is therefore on a voluntary basis. In view of the periods estimated for the development of silicosis in the various industries under present conditions, the consensus is that it is too early to expect results as to the efficacy of the method in workers receiving the treatment from the beginning of silica exposure.

Roentgen Evidence: Has any roentgen evidence accumulated with respect to the prevention of progression of silicosis by administration of aluminum? We have been informed by Dr. Riddell[27] of the Silicosis Referee Board of Ontario that in some of the mine workers the disease is progressing as shown by roentgenologic examination despite continual administration of aluminum, and in certain workers it has progressed on to definite silicosis since the beginning of the aluminum procedure. However, these men had various periods of exposure prior to commencing treatment. Systematic statistical data are not yet available. It should be mentioned that all mine workers are subject to an annual periodic examination by radiologists of the Workman's Compensation Board of Ontario.

---

[26] Denny, J. J.; Robson, W. D., and Irwin, D. A.: The Prevention of Silicosis by Metallic Aluminum: Preliminary Report, Canad. M. A. J. **37:** 1-11 (July) 1937; The Prevention of Silicosis by Metallic Aluminum, ibid. **40:** 213-228 (March) 1939.

Information has also been received from Dr. Riddell[28] concerning roentgenologic progression in 43 miners who had been therapeutically treated with a varied amount of aluminum by Crombie and associates[9] during the years 1940 to 1942, inclusive. On roentgenologic examination of 39 of these men in December 1945 by Dr. Riddell, 41 per cent presented extension of silicosis. Another group of 39 underground miners already referred to as treated by Dr. Robson,[25] of the McIntyre Research Foundation, were examined in 1943 and 1944. In 1942 these were presilicotic with the exception of 4 who were classed as having early silicosis. Thirteen, or 33 per cent, had moved to a higher roentgenologic category in December 1945.

As Dr. Riddell pointed out, the numbers involved in these groups are small and do not as yet warrant definite conclusions. The fact, however, is established that progression of silicosis did occur eventually after treatment with aluminum in these groups. It should be stated that the therapeutic dosage is stipulated as fifty times the prophylactic, but these findings do not exclude the possibility that still higher dosages might halt progression. Treatment has necessarily been conducted on an arbitrary basis, as there is no experimental basis in man by which to select optimum dosage.

### CRITERIA FOR RESEARCH IN EVALUATION OF ALUMINUM PROPHYLAXIS IN INDUSTRY

The opinion has been expressed from various sources that the decision of the McIntyre Research Foundation to introduce aluminum prophylaxis on a mass scale in industry should have been deferred, pending scientifically controlled research in man. This implies a consideration of (1) the main criteria involved in such research and (2) the feasibility of applying such criteria under industrial conditions.

*Control Groups.*—Control groups require precisely the same clinical and roentgenologic observation and record keeping as the test personnel. The selection of such groups should be unrestricted and made on the basis of adequate numbers, age and previous and present occupational exposure, in comparison with those of the treated workers. The selection of individuals to compose the two groups should be made in accordance with accepted statistical technics.

*Silica Dust Exposure.*—Dust counts, particle size and free silica analyses should be done at sufficiently frequent intervals to insure an accurate recording of exposure conditions. The determination of free silica in mixed dust should preferably be conducted by the roentgen ray diffraction method, which insures accurate analysis regardless of the size of the particles.

*Roentgenologic Data.*—Roentgenologic examinations must be of such a standard that roentgenograms are satisfactorily comparable year by year. This will demand an acceptable uniform technic in all plants included in the study.

*Period Essential for Such an Experiment.*—This would be contingent on the time required to produce silicosis in any particular industry under the engineering conditions of dust control maintained. Another variable relates to individual susceptibility. The protective mechanism against silica is so subnormal in some men that they begin to show roentgenologic evidence early in an environment apparently safe for most workers. Making due allowance for isolated cases where effective dust control may be impracticable, we must think in terms of ten, twenty or thirty years as the probable exposure time necessary for the development of silicosis in the great majority of men previously unexposed.

*Organization of an Experiment in Industry.*—This will require the services and facilities of some permanent research group—for example, an independent research agency or foundation, or a university research unit—the McIntyre Research Foundation to function in cooperation with such an organization. This would require a full time field unit made up of medical and industrial hygiene personnel, with a continuing group of roentgenologists available at headquarters and facilities for the assembling and analysis of statistical data. One would also be confronted with the considerable problem of securing funds for a project over a prolonged period of indefinite duration.

*Feasibility of Such an Experiment in Industry.*—It appears doubtful that selected control groups would ever be available in industry. The objections which both management and labor would raise to a frankly experimental plan to continue from ten to twenty years are too obvious even to mention. Even with full employee participation authorized, motivation would be lacking except possibly through financial reward. Absenteeism and turnover would also be deterrents.

Another imponderable is dosage. There is at present a complete lack of knowledge as to what proportion of aluminum actually reaches the pulmonary alveoli in man and becomes effective. The present dosage was adopted by extrapolation on the basis of Irwin's findings that 2 to 7 per cent of aluminum powder inhaled by rabbits was retained in the lungs after exposure to a known and constant concentration over a period of several months. Silicosis is a chronic disease produced only by many years of significant exposure to silica dust. It would be wholly impracticable to determine the effective prophylactic dose by repeated controlled trial and error, as might be feasible if an acute disease of relatively rapid development were under investigation.

Still another consideration is the possible effect of improved dust control. The McIntyre Research Foundation has stipulated that the introduction of aluminum prophylaxis is contingent on improved silica dust control to be maintained consistent with the generally accepted standards. If the incidence of silicosis were found experimentally to be of a negative order in both control and test groups, the result in both would be ascribed to dust control and no knowledge would be gained as to the aluminum factor.

On the basis of the foregoing discussion, it is not believed that a scientifically controlled experiment in industry on the aluminum prophylaxis of silicosis would be feasible except under the following conditions: (1) where silicosis would be expected to develop in a majority of the workers in a comparatively short period—for example, not exceeding five years—resulting from a situation in which efficient engineering dust control was impracticable and (2) where an adequate number of exposed personnel would be available as a control group.

---

[27] Riddell, A. R.: Personal communication to the author, Feb. 8, 1949.
[28] Riddell, A. R.: Personnal communication to the author, Feb. 25, 947.

*Present Status of the McIntyre Research Foundation.*—As the work is at present organized, there is no certain prospect of any future evaluation of aluminum prophylaxis. One of the main reasons is the lack of control groups for comparable study. Although such are probably not available in industry, as already discussed, it has been suggested that workers classified as refusing treatment be utilized as control subjects. The number of such personnel may be considerable. Dr. Herring,[29] medical director of a group of six potteries of East Liverpool, Ohio, and vicinity, reported that 338 men, free from silicosis, refused to receive aluminum prophylaxis over a three year period, all men being continuously employed during this time. We have also been informed [30] that 577 employees distributed through four silica brick plants in Pennsylvania where aluminum prophylaxis is in operation declined to receive prophylaxis over approximately the same period.

Could a sufficient number of selected men be induced to volunteer for the control phase, fully cooperating in the clinical and roentgenologic examination as required for the treated groups? It appears unlikely that many men could be relied on for sustained cooperation. The reasons impelling them to decline treatment would also tend to prevail in relation to a control program. Moreover, the utilizing of men in this category would entail disadvantages in contrast to a control group freely selected as such. As already emphasized, the groups should be reasonably comparable in distribution as to numbers, age and past and present occupational exposure. The control of these factors might be entirely inadequate if the subjects were limited to those refusing treatment. However, if such men were willing to consent only to periodic roentgenologic examination and to supply data on their occupational histories, it would be worth while. This possibility should be fully explored.

The following action is essential if the McIntyre Research Foundation is to solve the aluminum prophylaxis problem: (*a*) Select an industry for the experiment, if available, where there is still a hazard of silicosis despite modern engineering methods of dust control and where the disease would develop within approximately five years. (*b*) Conduct a comprehensive survey in that industry in order to determine whether an adequate and properly selected number of control subjects would be available from workers declining aluminum administration. (*c*) If satisfactory control groups can be obtained, take steps to staff the foundation with the necessary facilities and full time research personnel to organize and conduct the study.

*Accomplishments of the McIntyre Research Foundation.*—The foundation has made significant contributions to occupational hygiene by requiring its licensees to install and maintain adequate dust control in accordance with modern accepted standards and by stipulating that medical departments be organized in all such plants, staffed with industrial physicians and nurses.

Another important result is the demonstration that aluminum is not harmful to the normal and silicotic human lung in amounts given for therapy and prophylaxis of silicosis. While no statistical report on this aspect has come to our attention, the fact is generally known that mass administration in Canada and the United States involving many thousands of men has been negative with respect to the possible toxicity of aluminum. While statistical data are not as yet available concerning the possible adverse effect of aluminum in relation to early tuberculosis in man, the present impression from its widespread use is that it has no effect one way or the other in the amounts used for either prophylactic or therapeutic administration.

## SUMMARY

1. Studies on the therapy of silicosis thus far have been inadequately controlled. The majority of subjects have reported subjective improvement, apparently of psychic origin. No convincing evidence of objective improvement either of pulmonary function or by roentgen ray has been forthcoming. Certain cases have shown eventual progression by roentgen ray subsequent to aluminum therapy under present conditions of dosage.

2. It is too early to expect evidence of the effectiveness of aluminum prophylaxis in men who do not have a history of exposure to silica dust prior to the beginning of the treatment. It is a fact that certain Canadian miners with a history of previous exposure have shown roentgenologic progression despite treatment with aluminum, although statistical data are not as yet available.

3. Aluminum is apparently not harmful to the normal or silicotic human lung in the dosages given for the therapy and prophylaxis of silicosis. Whether or not it increases susceptibility to tuberculosis is unproved. As far as we can ascertain the mass administration of aluminum in the United States and Canada over the past five to six years has not had an unfavorable effect in this respect, although again statistical data are not yet provided. However, great care should be taken to exclude the tuberculous in selecting persons to receive aluminum therapy.

4. It is not believed that a scientifically controlled experiment in industry is feasible for the evaluation of aluminum for the prophylaxis of silicosis. This follows from the uncontrollable variables inherent in the industrial situation and other factors which have been discussed. For these reasons, it appears improbable that any research agency would consider it advisable to undertake such a project except under special conditions already discussed, and which may not be attainable.

5. The McIntyre Research Foundation, as presently organized, is not equipped to solve the aluminum prophylaxis problem in relation to silicosis. The steps considered necessary to accomplish this objective are outlined.

6. Research should be continued with laboratory animals with the object of finding a more adequate basis for application to man. Such study is now included in the program of the Saranac Laboratory of the Trudeau Foundation.

## Q FEVER

Q fever is an acute specific rickettsial disease of man characterized by a high grade fever, headache and malaise; often the disease is misdiagnosed as influenza or atypical pneumonia. Davis and Cox in Montana recovered the causative agent of Q fever from the tick, Dermacentor andersoni, several years before the disease itself was recognized. In Australia, Derrick in 1937 reported 9 cases of a new condition occurring in Queensland, which he named "Q fever." Eight of the 9 patients were slaughterhouse workers. The causative agent was named Rickettsia burneti after Burnet, who isolated the organism and recognized it as a rickettsia. Dyer demonstrated that Rickettsia diaporica, described by Cox, was similar to the causative agent of the Australian disease and was serologically and immunologically identical. Because of certain variations and because the causative agent of Q fever shows greater resistance to physical and chemical agents than other rickettsiae, the organism of Q fever represents a new genus, Coxiella; hence Coxiella burnetii supersedes R. burneti and R. diaporica.

According to Dyer[1] the belief that the name Q fever was given the disease because it was first described in Queensland, Australia, is erroneous; the name Q fever was given to the disease by Derrick, "Q" standing for "Query."

The disease has been found in the United States in Texas, Illinois, Montana, Arizona and California. Q fever outbreaks occurred in United States Army troops in Italy and Corsica. The disease was also reported from the Balkans, Switzerland and Panama.

During March 1946, an explosive outbreak occurred in Amarillo. The disease, according to Topping and co-workers,[2] affected primarily those engaged in killing the animals and handling the freshly killed meat. While the cattle can be infectious for stock handlers, the cattle themselves did not appear ill or exhibit any remarkable gross pathologic conditions during processing. The diagnosis, as reported by Irons and co-workers[3] was established primarily on the basis of laboratory procedures, with particular reference to increasing complement fixation titers during convalescence and after recovery. The Amarillo epidemic of Q fever represents the first sizable outbreak of this disease acquired naturally in the United States. With serums obtained in convalescence, results of complement fixation tests and rickettsial agglutination tests almost without any exception were positive for Q fever. The cases were similar except for wide variations in the severity of the illness, which ranged from mild influenza-like attacks to grave illnesses with 2 deaths among a total of 55 persons affected. Characteristic of the disease was an abrupt onset associated with frontal headache, chilly sensations and general malaise, fever of five to fifteen days' duration, essentially normal white blood cell count, roentgenologic evidence of pulmonary lesions, with minimal symptoms and physical signs referable to the respiratory tract, and comparatively rapid convalescence. Cutaneous manifestations were not observed. The serologic studies indicated that the illnesses were Q fever. A similar outbreak of more than 30 cases occurred in August 1946 among men working in the sheep and calf-killing department of one of the largest packing houses in Chicago.

Reports comprising clinical data on 625 cases were collected from six countries. The pathologic changes were found, in an analysis by Huebner and co-workers,[4] to have been caused in each instance by C. burnetii. The average incubation period was sixteen to eighteen days, with a minimum of thirteen days and a maximum of thirty-two days. Fever was the most consistent sign of the disease. Headaches were recorded in more than 90 per cent of the cases. The almost complete absence of abnormal changes in the upper respiratory tract in Q fever provides an important aid in differentiating that illness from such common illnesses as influenza, common cold, sinusitis and throat infections. All the usual blood serum agglutination tests were negative in result, including the Weil-Felix test and tests for brucellosis and typhoid. Reactions to cold agglutination tests were consistently negative, as were those to complement fixation tests for influenza, psittacosis and rickettsial diseases other than Q fever.

The disease has been found in California in sixteen counties in less than one year. In Los Angeles County, where Q fever appears to be endemic, more than 300 cases and 3 deaths have been studied. C. burnetii was present in the raw milk supply of four of five widely separated dairies in the Los Angeles area. The role that infected milk may play in human infection has not been determined. Two thirds of the patients so far studied did not use raw milk, nor was it used in their households. The mode of infection therefore must be other than personal or household use of raw milk. Proximity to livestock, however, appears to influence the occurrence of illness. The great majority of reported cases have occurred in adult males. On the basis of actual recovery of C. burnetii, human beings, cows, goats, sheep, bandicoots and ticks can be regarded as known natural reservoirs of Q fever. C. burnetii has been recovered from blood, urine and sputum of persons ill with Q fever. Despite these observations, infected persons are not apparently a source of human infections; indeed, there is much evidence to the contrary.

## HEALTH EDUCATION OF THE PUBLIC

Attention was called in THE JOURNAL last week to significant changes in the Principles of Medical Ethics adopted by the House of Delegates of the American Medical Association at its meeting in Atlantic City this year. Among the most important of the changes and additions are those related to education of the public regarding health and disease and dissemination of information to the public regarding medical affairs in general. The Principles of Ethics previously covered this aspect of medical relations to the public, by this statement in chapter III, section 4, on advertising:

> . . . It is equally unprofessional to procure patients by indirection through solicitors or agents of any kind, or by indirect advertisement, or by furnishing or inspiring newspaper or magazine comments concerning cases in which the physician has been or is concerned. All other like self laudations defy the traditions and lower the tone of any profession and so are intolerable. . . .

Also under chapter IV, section 1, appeared the statement:

> Physicians, as good citizens and because their professional training specially qualifies them to render this service, should give advice concerning the public health of the community. . . .

Again, under section 2:

> Physicians, especially those engaged in public health work, should enlighten the public regarding quarantine regulations; on the location, arrangement and dietaries of hospitals, asylums, schools, prisons and similar institutions; and concerning measures for the prevention of epidemic and contagious diseases. . . ..

And in section 3:

> Physicians should warn the public against the devices practiced and the false pretensions made by charlatans which may cause injury to health and loss of life.

In the Principles of Ethics as now revised these subjects are covered in the following statements:

> Chapter I, section 4:
> Among unethical practices are included the not always obvious devices of furnishing or inspiring newspaper or magazine comments concerning cases in which the physician or group or institution has been, or is, concerned. Self laudations defy the traditions and lower the moral standard of the medical profession; they are an infraction of good taste and are disapproved.

The distinction between material of this type and legitimate health education of the public is covered in the new Principles of Ethics in a much more elaborate statement, in chapter I, section 5, entitled "Educational Information Not Advertising," which follows:

> Many people, literate and well educated, do not possess a special knowledge of medicine. Medical books and journals are not easily accessible or readily understandable.
>
> The medical profession considers it ethical for a physician to meet the request of a component or constituent medical society to write, act or speak for general readers or audiences. The adaptability of medical material for presentation to the public may be perceived first by publishers, motion picture producers or radio officials. These may offer to the physician opportunity to release to the public some article, exhibit or drawing. Refusal to release the material may be considered a refusal to perform a public service, yet compliance may bring the charge of self seeking or solicitation. In such circumstances the physician should be guided by the decision of official agencies established through component and constituent medical organizations.
>
> A physician who desires to know whether, ethically, he may engage in a project aimed at health education of the public should request the approval of the designated officer or committee of his county medical society.
>
> The most worthy and effective advertisement possible, even for a young physician, especially among his brother physicians, is the establishment of a well merited reputation for professional ability and fidelity. This cannot be forced, but must be the outcome of character and conduct. The publication or circulation of simple professional cards is approved in some localities but is disapproved in others. Disregard of local customs and offenses against recognized ideals are unethical.
>
> The promise of radical cures or boasting of cures or of extraordinary skill or success is unethical.
>
> An institution may use means, approved by the medical profession in its own locality, to inform the public of its address and the special class, if any, of patients accommodated.

This section is a recognition of the extent to which the medical profession is already engaged in education of the public regarding health and disease. Many medical societies now conduct radio programs in which physicians speak and are introduced with reference to their names and the positions that they hold. Many medical organizations publish pamphlets by the thousands or millions, and these are widely distributed to the public. These pamphlets carry the names, addresses and qualifications of the physicians who prepare them. *Hygeia,* the magazine published by the American Medical Association for education of the public, does not hesitate to include the names of physicians who contribute articles and personal information concerning them to indicate their qualifications. Many physicians, including both those in and out of practice, now write magazine articles and books for education of the public, and these books have large circulation. The contrast between the conditions that prevail today and those that existed as late as twenty-five years ago is startling and represents a complete change in the point of view of the medical profession on the difference between education of the public and the use of public information to promote the practice of an individual physician.

Medical practice has become so largely centered in the hospital that these institutions also have felt the pressure of the public for information not only concerning health and disease in general but concerning patients who enter the hospitals and whose conditions may be matters of public importance. Most large hospitals now have officials who devote their time to the public relations of the institution. Leaders in medicine recognize the necessity for information to the public regarding unusual conditions that may come to public notice or even the health of persons who are considered "newsworthy."

The limitations necessary to prevent infractions of medical ethics and good taste are clearly stated in the revised Principles of Ethics. The physician may always secure from the appropriate committee of his local medical society a decision as to whether or not any activity leading to public notice is within the bounds of what is considered decent or ethical. Institutions which propose to extend their influence on the local community may likewise have access to authoritative sources for advice or guidance. Once more the responsible officials of medical organizations who undertake to advise or guide or decide in matters of this type are cautioned to make their decisions on the basis of good experience and common justice. All should be aware of the possibility that the Principles of Ethics and the mechanisms established by medical organizations to make them effective may be used or abused by individual physicians or others who endeavor to employ the Principles and the mechanism as a means of satisfying their envy or their enmity toward other physicians or medical institutions.

## Current Comment

### DR. ALBERT SCHWEITZER—HUMANITARIAN

Universities, the press and various organizations are honoring Dr. Albert Schweitzer for his accomplishments in music, medicine and other fields. Eminent as an authority on Goethe and Bach and as a scholar for his interpretations of religion, Dr. Schweitzer also is well known as a physician who for over thirty years has treated the sick in French Equatorial Africa. His life has been filled with many accomplishments. At 74 years of age he is looking forward to his return to Africa to continue with his work. Before he began the study of medicine at the age of 30 years he had achieved international recognition and was renowned as musician, author and preacher. Notwithstanding such recognition, he chose to follow the life of a medical missionary. On the completion of his medical studies he went to Africa, where "they needed doctors." This philosophy, simply stated, reflects the sincerity of this world famous humanitarian. The medical profession is proud of Dr. Albert Schweitzer. His actions have evealed more clearly than words that the motivating rce of his life has been service to humanity.

### CARE OF THE PARAPLEGIC

THE JOURNAL, during the last two weeks, has published an extended consideration of the care of the paraplegic patient. The National Paraplegic Foundation, which is concerning itself particularly with veterans who have suffered from these seriously disabling injuries, sponsored the article through its medical advisory committee. Among the agencies that have been concerning themselves particularly with the paraplegic patient is the 52 Association, Inc.,[1] organized with the specific purpose of doing everything possible to make life worth while for the veteran who has become disabled through injuries to the spine that make the lower half of the body incompetent. Any physician who reads the intensive detail involved in the scientific care of such patients will realize that laymen who devote their time, their funds and their efforts to bringing some happiness into the lives of those who have given of themselves so fully toward the winning of the war deserve the utmost encouragement and assistance. The 52 Association deserves support, particularly by physicians who know how important is the mental attitude of the disabled patient.

### NATIONAL SCHOOL HEALTH SERVICES ACT

For many years the American Medical Association has collaborated with the National Educational Association and many other groups in stimulating and in making effective programs for improving the health of school children by the detection of correctable defects and by guidance in securing adequate attention to such defects. The National School Health Services Act passed by the Senate provides federal funds under state control to extend the school health program. Section C of this Act (S. 1411) would provide use of school health services for the prevention, diagnosis and treatment of physical and mental defects and conditions. Annually $35,000,000 would be distributed to the states that have developed plans approved by the Federal Security Administrator. The bill does say that the treatment would be provided whenever the parents of the children are unable to provide it. However, a state plan may provide for the prevention and treatment of physical and mental defects of all school children, irrespective of the financial status of the parents. This bill was described in detail in THE JOURNAL for May 28, 1949, page 411. At the annual session of the Association in Atlantic City the House of Delegates adopted a resolution instructing the Board of Trustees to undertake measures to prevent the enactment of this legislation. The Secretary of the Association has sent a letter concerning the resolution to the secretary of each state and territorial medical association. The measure has not yet been considered by the House of Representatives. Obviously the next step is to call the attention of members of the appropriate committee of the House of Representatives to the invasion of the practice of medicine involved in this procedure.

---

1. The 52 Association, Inc., now has offices in Chicago, 111 North Canal Street, Room 800; New York, 840 Eighth Avenue; Miami, 420 Lincoln Road, Miami Beach. Other branches are in process of organization.

# ORGANIZATION SECTION

## SCHOOL HEALTH SERVICES

### Statement Submitted to Sub-Committee on Public Health, Science and Commerce, of the Committee on Interstate and Foreign Commerce of the House of Representatives

I am Walter B. Martin, a practicing physician of Norfolk, Va. I am appearing as a member of the Board of Trustees of the American Medical Association. This association had a membership as of May 1, 1949, of 142,882 physicians.

I am here to express opposition to H. R. 3942 and other identical bills as they are now drawn. We are in agreement with the general purpose of the bill as stated in Section 2. We desire to see the health service for children of school age improved to the end that each child will have an opportunity to grow to maturity unhampered by preventable diseases or conditions. As in all endeavors in the field of social welfare, this is an ideal and not possible of complete realization in the present state of our educational, political and moral progress. We agree that there is a real need of an improved health service for school children and that lack of funds in some areas has and will retard the development of a proper program.

The question for consideration therefore is whether the plan proposed in this bill as now written provides the best means of accomplishing its objectives. We believe not, without some very definite and radical changes. The fundamental purpose of the bill is so worth while that we would not oppose it if we did not feel that in its present form it would fail to accomplish its purpose. Our objections are directed to certain basic principles involved and to some specific details.

The whole question of federal subsidy and of the partition of tax resources between the federal, state and local governments needs to be reexamined and reevaluated. The flow of the major fraction of our tax money into the federal treasury and its distribution to the several states in the form of subsidies is a dangerous procedure, and if not properly safeguarded, threatens the security of our form of government. The tax resources of localities and states have become so depleted that they are unable to carry out needed and worth while projects without federal aid. The evil of this becomes apparent when we see federal subsidy used as a club to compel the adoption by the states of certain procedures not at the time acceptable to all of the states, and at times contrary to their political and moral philosophy, and even their laws.

Federal control to a greater or lesser degree follows the distribution of federal subsidy. Since these funds are appropriated from the federal treasury, it is assumed that some form of federal administration and control must be set up. In this bill, the administrative provision follows the familiar pattern. A federal agency is designated to administer the act, and the head of that agency becomes the administrator. He is granted then the power to make such regulations as are necessary to carry out the purpose of the act. The states, through their governing bodies, are required to accept the provisions of the act as written. The states are then required to submit a plan acceptable to the federal administrator. If he fails to approve of a plan or, after a plan is in operation, disapproves its manner of operation, he can block completely the flow of federal funds to that state.

Recourse may be had to the courts, but by the very wording of this Act, the outcome of the appeal is weighted in favor of the federal administrator, since paragraph (*b*) of Section G states, "The findings of the facts by the Federal Administrator unless substantially contrary to the weight of evidence shall be conclusive."

In the event a state law prevents the state from accepting a part or the whole of the act, the administrator is empowered to invade the state and set up machinery within the state to carry out the purpose of the Act.

The assumption that a federal administrator is wiser, more honest, more patriotic and more devoted than any of the administrators of the several states is not in fact true, but is one that is commonly made. This idea goes straight back to the old theory that some special virtue resides in the Administrator of the Supreme Government and is contrary to democratic principles.

This Act brings federal administration into close contact with every elementary and secondary school in the country. From the standpoint of medical care this is particularly objectionable. It is our belief that the primary responsibility for the health of an individual rests on himself or his family, then on the local community and next on the state. The intrusion of the federal government into the picture is objectionable and should only take place when the situation to be corrected affects in fact the national welfare or safety. The setting up of any one pattern in all states is unnecessary and harmful to true progress, since it prevents experimentation and destroys initiative, not only in the state and local government, but also in the individual. If 29,000,000 children are to be taught that their health service must stem from the federal government, then in one generation the road to complete federal control of medicine will be open.

We believe that it is highly desirable that additional funds be made available for the purpose of improving medical service to children and for moving toward the objectives stated in the preamble of this bill. We believe that federal control in the administration of the bill is harmful. The Congress should lay down broad general controls in the bill. The only necessary administrative controls should be a proper audit of funds to determine that they have been honestly administered. If any state carried out the basic provisions of the bill in such a way as to react harmfully or unjustly to any group, an appeal to the appropriate federal court would be effective.

Aside from these general objections, there are certain specific details that we feel should be considered most carefully.

1. The bill straight-jackets the planning of a state, although the state and localities must put up an amount of money equal to that furnished by the Federal government. State plans should vary according to the specific needs in the several states.

2. No recognition is given to the important fact that medical care is an individual matter and can best be given by a physician of the patient's choice. If carried out on a group basis, or by salaried employees, an impersonal type of medical care may develop that while mechanically excellent may lack the soul and spirit that makes medical service most effective.

3. Paragraph 7, page 8, sets up a state advisory committee, but there is no requirement that any member of this committee shall be a doctor of medicine. The provision of good medical care is a complex and highly technical procedure, yet the importance of the physician in the direction of the program is not recognized.

4. On page 6, paragraph (*c*) the way is made open for providing medical care to all children regardless of the ability of their parents to pay for such treatment. We can see no justification for expenditure of tax funds for this purpose, nor does this provision come within the scope of the general purposes of the bill as stated in Section 2. It would greatly increase the work load of any organization set up to carry out the program and lead to deterioration in the quality of care rendered those who most need the service. Such a provision would add greatly to the cost and would link this bill with other bills that have a definite socialistic purpose.

We hope that this bill can be so altered that its main purpose of improving medical service to school children can be accomplished without violating sound principles of democratic government.

## MEDICAL AND BIOLOGICAL ABSTRACTING CONFERENCE HELD BY UNESCO

### Report by Dr. Henry Viets, Representing the American Medical Association

The Interim Coordinating Committee on Medical and Biological Abstracting of the United Nations Educational, Scientific and Cultural Organization held its first full session at Unesco House, Paris, June 1-4, 1949.

Dr. Hugh Clegg, the editor of the *British Medical Journal,* acting as chairman, reviewed its activities since 1946. Toward the end of the war the British Medical Association made plans to establish a medical abstracting service as soon as conditions should permit. At about the same time, a group of scientists in Amsterdam announced their intention of publishing an abstracting journal in the English language under the title *Excerpta Medica.* A Coordinating Committee was established in UNESCO, largely through the efforts of Dr. I. M. Zhukova of the Department of Natural Sciences. A number of meetings were held, and among the resolutions passed was one denoting that it was considered undesirable to duplicate specialist abstracting journals and that a comprehensive abstracting service, in the sense of abstracting all articles of all journals, was neither possible nor desirable. An effort should be made toward collaboration by the exchange of abstracts, thus avoiding duplication of abstracting sections. In addition, the importance of establishing a common method of abbreviating titles of periodicals was emphasized, and the resolution passed favored the method used by the *World List of Scientific Periodicals.* At present, as pointed out by Dr. Clegg, uniformity in the method of abbreviating titles or in arranging the bibliographic entry to an abstract does not exist. In addition, confusion prevails in the use of symbols and abbreviations.

Prof. M. W. Woerdeman, editor in chief of *Excerpta Medica,* indicated it would not be possible to satisfy the many divergent interests by a single abstracting service. When a scientific article is of interest to more than one group of readers, it is probably preferable to have it abstracted by different experts, who alone would know the special interests of their particular groups. Any attempt to centralize abstracting work would lead to this being overlooked. Most of the overlapping which occurred was in preparation rather than in the publication of abstracts. For less well known languages, Professor Woerdeman suggested that the various abstracting agencies might jointly use the common offices in the countries of these languages.

The arrangement of the abstract entry was discussed by Dr. Isabella Leitch, director of the Commonwealth Bureau of Animal Nutrition in the United Kingdom. She suggested that the following order should be considered: (1) author's name, (2) the place where the work was done, (3) the full title of the paper, (4) a translation, not necessarily literal, of the title and (5) the name of the journal, year of publication, volume, part number and first and last pages of the paper.

Although it was pointed out by Dr. G. M. Findlay, editor of *Abstracts of World Medicine,* published under the auspices of the British Medical Association, that the Royal Society Conference on Scientific Information showed that most journals place the title of the paper first in order, the committee voted heavily in favor of the order suggested by Dr. Leitch.

Mrs. Eileen R. Cunningham, representing the Medical Library Association of the United States of America, gave an analysis of the results of a survey which she had made of medical libraries in North America and elsewhere. A large majority of the librarians were in favor of standardizing the form of bibliographic data and advocated that the author's name should come first. Most of the librarians, moreover, expressed a preference for the informative against the indicative type of abstract.

The point of view of the user was also expressed by Prof. P. Lépine, representing the Institut Pasteur of Paris. Professor Lépine urged speedy publication and noted that most of his colleagues preferred a short abstract published quickly rather than a long abstract which might appear many months after the publication of the original article.

Dr. Marguerite Lwoff, representing the *Bulletin de l'Institut Pasteur,* France, presented an extensive review of the use of abbreviations, contractions and symbols. She found much variation in different countries.

Dr. G. M. Findlay presented a survey of the work done by the Royal Society Conference on Scientific Information and pointed out the difficulties which editors of abstract journals have to meet. It was often difficult to find out what medical and biologic journals were actually being published in different parts of the world, and, because of currency and other obstacles, journals were often unobtainable. He urged that a full list of medical and biologic journals should be published and brought up to date at six month intervals. Dr. Findlay expressed disapproval of authors' abstracts, but it was pointed out by other members of the committee that one of the strongest arguments for their use was the existence of *Biological Abstracts,* edited by Dr. J. E. Flynn, who relied on these largely in the compilation of his periodical.

The matter of editing and informing was further discussed by Dr. Charles Wilcocks, director of the Bureau of Hygiene and Tropical Diseases, London. He expressed a view that accuracy, rather than promptness, should be the first consideration of an editor of an abstract journal and that continuity of interest could be maintained only by continuity of editing. He described how the *Tropical Diseases Bulletin* and the *Bulletin of Hygiene* had evolved in response to these needs.

The committee ended its conference by formulating certain proposals which were passed on to UNESCO and in making some recommendations which, it is hoped, will in time be adopted by abstracting organizations. (1) It asked UNESCO to publish a list of medicobiologic journals with the system of abbreviations adopted by the *World List.* It was also recommended that in such a list there should appear opposite the journal titles symbols to indicate which abstracting organizations included them in their survey. (2) The committee also asked UNESCO to collect information on abbreviations and symbols used in medicobiologic literature and to consider publication in a form suitable for use by abstracting services, editors and scientists. (3) It adopted the proposal made by Dr. Leitch for the method of arranging the bibliographic entry to an abstract. Also, it urged that UNESCO continue its efforts to promote a free exchange of medical and biologic journals among different countries.

The committee advocated the universal use of the metric system for weights and measures and the centigrade system for recording temperatures in medical and biologic communications. It was recommended, moreover, that editors of medical and biologic journals should adopt greater uniformity in terms and greater precision in the papers appearing in their journals.

---

## PLANNING FOR CIVILIAN DEFENSE

Following a directive by the President calling on the National Security Resources Board to develop a program of civil defense planning under civilian control, the acting Chairman of the Board, John R. Steelman, has announced assignments of phases of civil defense planning to be undertaken by various federal agencies. The agencies which would participate in the planning are: Atomic Energy Commission; National Military Establishment; Federal Security Agency; Federal Works Agency, and the Departments of Agriculture, Commerce, Interior, Treasury and Justice, with other agencies to be added as needed. The National Security Resources Board will coordinate the planning within the federal government and will serve as the focal point of contact for civil defense planning between the federal government and states, municipalities and professional and trade organizations. The National Military Establishment has been assigned planning for civilian participation in defense against armed forces. This assignment will embrace planning for air raid warning systems, including civil air patrol and aircraft detection and identification; auxiliary antiaircraft, harbor and other defenses; and camouflage, protective construction and other physical measures of defense.

Leadership in developing a program of wartime disaster relief will be taken by the Federal Works Agency. This assignment will include plans for civilian and military participation in activities designed to minimize the effects of enemy attack, conventional or otherwise, on the civilian population and the nation's facilities and services, and for repairing the damage or injury resulting from such attack. The program will include plans for:

1. Medical supplies and services, including hospitalization, sanitation and blood banks.

2. Decontamination and measures to minimize the effects of chemical, radiologic and biologic or other unconventional attack.

3. Fire protection and fire fighting.

4. Emergency measures for the regulation of transportation and communications facilities and services and the restoration of order, including conditions under which martial law would be declared and methods for invoking it.

5. Rescue and evacuation, including feeding, clothing and sheltering.

6. Repair and restoration of water, gas, electric and sewage systems, including antipollution measures.

Demolition.

8. Formation and use, only in the event of war, of warden or auxiliary services and mobile battalions, whose members will be prepared to implement appropriate phases of plans developed for wartime disaster relief.

The planning of those internal security measures, such as prevention of sabotage and espionage, which are related to the civil defense program will continue to be coordinated by the National Security Council.

---

# Washington Letter

*(From a Special Correspondent)*

July 11, 1949.

### Priest Subcommittee Concludes Health Hearings

On July 7 the House health legislation subcommittee, of which Rep. J. Percy Priest is chairman, adjourned sine die the public hearings on the Thomas-Murray-Dingell and miscellaneous bills which had been under way since May 20. Concluding topics considered by the subcommittee were increased federal support of local public health departments and institution of a federal-state program of school health services.

Witnesses heard on public health units included Dr. W. Palmer Dearing, Acting Surgeon General of U. S. Public Health Service; Dr. Donald A. Dukelow, representing the American Medical Association; Dr. Valdo A. Getting, Massachusetts Health Commissioner and spokesman for the Association of State and Territorial Health Officers; Dr. Haven Emerson, in behalf of the National Health Council and the American Public Health Association; Dr. Edwin L. Crosby, director of Johns Hopkins Hospital and appearing in behalf of the American Hospital Association, and James G. Stone, for the National Tuberculosis Association.

All supported the principle of striving toward maximum coverage of the nation's population by efficient, well staffed local public health units. Dr. Dukelow, however, argued that legislation should define the scope of public health services rather than leave this point to be decided by a federal administrator; that provision should be made for an advisory council; that powers vested in the Surgeon General should not be too broad and, finally, that state agencies have the right to appeal rulings by the Surgeon General to the advisory council or even to the courts.

Similarly, most of the witnesses heard on federal support of school health services endorsed this project in principle, but some raised objections to certain details. Dr. Joseph S. Wall, representing the American Academy of Pediatrics, recommended that the diagnostic and therapeutic services contemplated be restricted to children of families financially unable to pay for such services. He also suggested an amendment the effect of which would be to give the family physician a larger role in the proposed program.

Federal Security Administrator Oscar R. Ewing testified in support of the program, as described in Title V of the Thomas-Murray-Dingell omnibus bill (H. R. 4312, S. 1970).

Dr. Walter B. Martin of Norfolk, Va., appearing as a member of the American Medical Association Board of Trustees, testified that while the aims of the proposed legislation are meritorious, several amendments are indicated in order to minimize dangers of bureaucratic control, indiscriminate distribution of services without regard to economic status and inadequate recognition of the medical profession in formulation of policies.

"We hope that this bill," he said, "can be so altered that its main purpose of improving medical service to school children can be accomplished without violating sound principles of democratic government."

Among other witnesses were George J. Hecht, chairman of the American Parents Committee; Joseph M. Babcock, of the American Optometric Association; Ben H. Gray, national director of the National Epilepsy League, and Selma M. Borchardt, vice president of the American Federation of Teachers.

At the adjournment of the hearings, Chairman Priest said that possibly one or two more sessions may be held to hear testimony by sponsors of an all-Republican bill which would provide for federal subsidization of voluntary prepayment medical and hospital care plans.

### Study Sections of National Institutes Reorganized

Reorganization of the study sections and advisory panels which participate in allocation of millions of dollars annually in federal medical research grants has been completed by National Institutes of Health. Certain sections have been abolished or consolidated, and new ones have been added. The net result has been a reduction of the number of sections from twenty to seventeen. The name of the bacteriology study section has been changed to microbiology and immunology. Sanitation has become environmental health. The panels on antibiotics, tuberculosis and syphilis have been consolidated as a single section on experimental therapeutics. The malaria section has been absorbed by tropical medicine. There is a new study section on morphology and genetics and another on arthritis and rheumatism. The gerontology and radiobiology sections have been disbanded, although the scientists who were members of the former have been invited to stay on in a consultative capacity. Officials of National Institutes of Health emphasized that dissolution of these two sections resulted from the paucity of grant applications and the practicability of distributing their functions over other sections, and should not be interpreted as foreshadowing any diminution of interest in gerontologic and radiobiologic projects.

August 1 is the deadline for receipt of research grant applications intended for review at the fall meetings of the advisory panels and study sections. December 1 is the dealine for consideration at the midwinter meetings and April 1, 1950, for the spring meetings.

### Colonel Seeley Heads Walter Reed Surgical Service

Col. Samuel F. Seeley (M.C.), U. S. Army, who served as executive officer of Procurement and Assignment Service in 1941-1942, has assumed his new post as chief of surgical service at Walter Reed General Hospital in the nation's capital. He relieves Col. Frank E. Hamilton, transferred recently to Gorgas General Hospital in Panama. Since 1946 Colonel Seeley had been chief of surgery at Brooke General Hospital, Fort Sam Houston, Texas. A graduate of University of Minnesota School of Medicine, he is a specialist certified by the American Board of Surgery, and a member of American College of Surgeons and Alumni of Mayo Clinic.

---

# Coming Medical Meetings

Aero Medical Association, New York, Aug. 29-Sept. 2. Dr. Thomas H. Sutherland, 214 S. State St., Marion, Ohio, Secretary.
American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va., The Homestead, Sept. 8-10. Dr. Leroy A. Calkins, University of Kansas Medical Center, Kansas City 3, Kan., Secretary.
American Congress of Physical Medicine, Cincinnati, Netherlands Plaza Hotel, Sept. 6-10. Dr. Richard Kovacs, 2 E. 88th St., New York 28, Secretary.
American Roentgen Ray Society, Cincinnati, Sept. 4-7. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Iowa, Secretary.
International Congress of Biochemistry, Cambridge, England, Aug. 19-25. Lt. Col. Francis J. Griffin, 56 Victoria St., London, W.C.1, Organizer.
Montana State Medical Association, Butte, Aug. 1-4 Dr Herbert T. Caraway, 115 N. 28th St., Billings, Secretary.
National Medical Association, Detroit, August 8-12. Dr. John T. Givens, 1108 Church St., Norfolk, Va., Secretary.
Utah State Medical Association, Salt Lake City, Sept. 1-3. Dr. Ray T. Woolsey, 42 S. Fifth-East St., Salt Lake City 2, Secretary.
Vermont State Medical Society, Burlington, Sept. 1-2. Dr. James P. Hammond, 542 Main St., Bennington, Secretary.
West Virginia State Medical Association, White Sulphur Springs, The Greenbrier, Aug. 4-6. Mr. Charles Lively, 1031 Quarrier St., Charleston, Executive Secretary.

# GOVERNMENT SERVICES

## NAVY

### DR. KARSNER SWORN IN AS RESEARCH ADVISOR

Dr. Howard T. Karsner, former professor of pathology at Western Reserve University, Cleveland, was sworn in July 1 as medical research advisor to the Surgeon General of the Navy. He will assist and advise the Surgeon General, concerning evaluation, coordination and development of the Navy's Medical Research Program.

Dr. Karsner was recently given the honorary degree LL.D. by Western Reserve University. He is the author of a widely used textbook on "Human Pathology" and many scientific papers. He was the fifth Navy department employee to be appointed under the provision of Public Law 758, which authorizes the Navy to fill thirteen positions in the professional and scientific service above the salary limitations of the regular civil service.

### NEW REGULAR OFFICERS

The following young reserve medical officers on active duty have been appointed to the regular Navy Medical Corps:

Lt. Francis H. McCullough Jr., Jackson Heights, L. I., New York; graduated: Duke University School of Medicine.

Lt. (jg) Frank M. Bryan, Fort Myers, Fla.; graduated: Emory University School of Medicine.

Lt. (jg) Robert P. Dobbie Jr., Buffalo; graduated; University of Michigan Medical School.

Lt. (jg) George E. Gardner, Harrisburg, Pa.; graduated: Hahnemann Medical College.

Lt. (jg) James L. Keating, Falls Church, Va.; graduated: Georgetown University School of Medicine.

Lt. (jg) Raymond J. Lefiler, Sayre, Pa.; graduated: University of Iowa School of Medicine.

Lt. (jg) Francis P. Nash, E. St. Louis, Ill.; graduated: St. Louis University School of Medicine.

Lt. (jg) Edward J. Rupnik, Library, Pa.; graduated: University of Pittsburgh School of Medicine.

Lt. (jg) John W. Troy, Washington, D. C.; graduated: Georgetown University School of Medicine.

### DUTY UNDER INSTRUCTION

The following medical officers have been nominated for duty under instruction in the Graduate Medical Training Program:

Commander Robert B. Simons of LaJolla, Calif., to a residency in dermatology and syphilology at the Naval Hospital, San Diego.

Lt. Charles C. Bratenahl of Washington, D. C., to a fellowship in pathology at the University of Michigan, Ann Arbor, Mich.

Lt. (jg) Jules H. Bogaev of Philadelphia to a residency in urology at the Naval Hospital, Philadelphia.

Lt. (jg) Leland C. Brannon of Piedmont, S. C., to a residency in neurosurgery at the Naval Hospital, Long Beach, Calif.

Lt. (jg) William C. Trier of White Plains, N. Y., to a residency in general surgery at Grasslands Hospital, Valhalla, N. Y.

Lt. (jg) James H. Watts, Jr., of Ansley, Neb., to the University of Illinois College of Medicine, Chicago.

Lt. (jg) James E. Whiteside, of Decatur, Ark., to a residency in pathology at the Naval Hospital, Long Beach, Calif.

### RETIRED OFFICERS ON ACTIVE DUTY

A law signed by the President on June 25 provides for the retention on the active list of certain officers of the medical and dental corps of the Navy. Under the old law, that of 1947, staff captains who had completed 31 years of service faced the possibility of involuntary retirement. The new law provides that a certain number of captains, to be determined by the Secretary of the Navy, shall be continued on the active list to meet the needs of the service, with the provision that until June 30, 1952, no such officer should be involuntarily retired before the age of 62. At present, more than 40 captains in the Medical Corps are eligible for recommendation for continuation on the active list.

### VACANCIES IN THE MEDICAL SERVICE CORPS

The Surgeon General announces that 160 vacancies exist in the Medical Service Corps of the Navy. Qualified civilians are eligible for appointment in the pharmacy, optometry and allied sciences sections. Both male and female candidates may apply for these appointments. Interested personnel may apply to any office of Naval Officer Procurement; they should not apply directly to the Navy Department in Washington, as local offices are required to take first action in all such matters.

### FIRST ACTIVE DUTY

The following lieutenants (jg) in the Medical Reserve Corps have been nominated for their first active duty:

Morris L. Britton of Ballinger, Texas.
Owen W. Doyle of Buffalo.
Robert V. Dutton of Salisbury, N. C.
Frederick V. Light of Euclid, Ohio
John V. McAllister of Old Greenwich, Conn.
George W. S. Moore of Bluefield, W. Va.

### CERTIFIED BY BOARDS

The following additional officers have successfully passed the examinations of specialty boards: Captain Van C. Tipton, American Board of Preventive Medicine and Public Health; Lt. Commander Frances L. Willoughby and Lt. Albert J. Zuska, both have been certified in psychiatry by the American Board of Psychiatry and Neurology.

### PERSONALS

Captain James J. Sapero recently departed for Cairo, Egypt, where he will assume command of the United States Naval Medical Research Unit 3.

## AIR FORCE

### AIR FORCE IS HOST TO MEDICAL MISSION

Air Force Secretary W. Stuart Symington announces that the Air Force will be host to an Alaskan Medical Mission which will hold a conference at Anchorage, Alaska, from July 19 to August 1, under the joint sponsorship of the Department of Interior and the American Medical Association. Air Force and Army medical officers will participate in the two week conference.

The purpose of the conference, which will be conducted by five specialists chosen by the American Medical Association, is to provide Interior Department medical officers now serving at remote areas in Alaska with seminars, demonstrations, clinics and consultations based on the latest technics and developments in internal medicine, general surgery, obstetrics and gynecology, tuberculosis and ophthalmology.

The mission is scheduled to depart from Washington on July 16 by Air Force transport and will arrive in Alaska by July 18. Comprising the mission will be five specialists who will conduct the conference, ten physicians who will serve as replacements for medical officers now serving in Alaska, and representatives of the U. S. Air Force Medical Service. The Air Force will conduct a "round robin" flight to Alaskan outposts at Barrow, Juneau, Katzebue, Kanakanak, Tanana and Sitka, for the purpose of leaving replacements and flying physicians to the Anchorage conference.

# PUBLIC HEALTH SERVICE

## APPOINTMENTS

The last group of personnel appointments to accompany the administrative reorganization of the Public Health Service has been announced. Newly appointed to the Bureau of State Services is Associate Bureau Chief Dr. Joseph O. Dean. A new associate chief in the Bureau of Medical Services is Bruce Forsyth, D.D.S. Associate bureau chiefs carry the rank of assistant surgeon general.

A new division chief in the Bureau of State Services is John W. Knutson, D.D.S., whose assignment is to the Division of Dental Public Health. New appointments in the Bureau of Medical Services include Dr. Daniel J. Daley, who becomes Chief of the Division of Federal Employee Health; Dr. John Cronin, Chief of the Division of Hospital Facilities; Dr. John R. McGibony, Chief of the Division of Medical and Hospital Resources; Miss Margaret Arnstein, Chief of the Division of Nursing Resources, and Dr. G. Halsey Hunt, Chief of the Division of Hospitals. Dr. Dean is a graduate of the University of Nebraska College of Medicine and the Johns Hopkins University School of Hygiene and Public Health. He was commissioned in the Regular Corps of the Public Health Service in 1929. Dr. Forsyth entered the Public Health Service as an intern in 1931 and was commissioned in the Regular Corps in 1939. He received his degree in dentistry at the Michigan School of Dentistry, and did graduate work at the Mayo Clinic, Rochester, Minn., and the National Institutes of Health.

Dr. Knutson is a graduate of the University of Minnesota School of Dentistry and of the Johns Hopkins School of Hygiene and Public Health. He was commissioned in the Regular Corps in July 1934. Dr. Daley was graduated from Georgetown University Medical School, Washington, D. C., and since 1948 he has been chief medical officer of the Bureau of Maritime Services, U. S. Maritime Commission. Dr. Cronin is a graduate of the University of Cincinnati College of Medicine. He was commissioned in the Regular Corps of the Public Health Service in April 1934. Dr. McGibony is a graduate of the University of Georgia Medical School. Formerly he was detailed to the Office of Indian Affairs as Hospital administrator and later served that office as director of health. Miss Arnstein is a graduate of Smith College, Northampton, Mass., of Presbyterian Hospital School of Nursing, New York, and received a master of arts degree from Teachers College, Columbia University, and the degree of master of public health at Johns Hopkins School of Hygiene and Public Health, Baltimore. Dr. G. Halsey Hunt was commissioned in the Public Health Service in 1936 after several years of private practice in Red Bank, N. J. He graduated from the Columbia University College of Physicians and Surgeons.

## NEW CHIEF OF LABORATORY OF BIOLOGICS CONTROL

Dr. Milton V. Veldee, Chief of the Laboratory of Biologics Control of the Microbiological Institute will retire after twenty years at the National Institutes of Health. His successor as chief of the laboratory will be Dr. William G. Workman, former assistant chief, who has been at the National Institutes of Health for eighteen years.

The Laboratory of Biologics Control is charged with the immediate administrative responsibility for enforcement of the Federal Biologics Law. It conducts research in problems having to do with tests required to determine the quality of biologic products. As time permits, research is also conducted in problems related to improving methods of producing the various biologic products.

Dr. Veldee received his M.D. degree from Harvard University in 1919, served an internship at Massachusetts General Hospital and spent one academic year on the faculty of Johns Hopkins School of Hygiene.

Dr. Workman received his M.D. degree from Ohio State University in 1930, served his internship at the United States Marine Hospital in Baltimore and was commissioned in the Public Health Service in 1931. He was a consultant in preventive medicine to the U. S. Army in Korea and Japan and advisor to the military governments of those countries in 1946. He is at present a consultant to the Research and Development Board of the National Military Establishment. He is a Fellow of the American Medical Association, and a member of the Founders Group of the American Board of Preventive Medicine and Public Health.

## STUDY OF LUNG CANCER

The Surgeon General has approved thirty-six special cancer control project grants totaling $550,802. One of the grants is to the California State Department of Public Health, which will study factors in the human environment that may influence the development of lung cancer. This study is the sixth investigative project on environmental carcinogens aided by the National Cancer Institute—other aspects of this problem are under study in New York, Pennsylvania, Ohio, Colorado and New Jersey. The study of respiratory cancer in California will seek possible causal factors through employment history studies of some 500 cases of lung cancer. Where the history of the patient indicates possible occupational exposure, follow-up studies will be made to discover the suspected hazard and the feasibility of protective measures.

Grants were made to the University of Tennessee College of Medicine and the University of Kansas Medical Center for evaluation of a number of reported cancer diagnostic tests. This work will be coordinated with a project already under way at the University of Washington, which has also received aid from the National Cancer Institute.

Seventy-four of the 79 medical schools in the United States now have cancer training programs which are carried on with the aid of grants from the National Cancer Institute. Allocations totaling $872,477 have been approved by the Surgeon General. Similar grants aid cancer teaching in 36 of 40 dental schools in the United States.

## ADVISORY COMMITTEE ON INDUSTRIAL HYGIENE

The newly appointed advisory committee to the Public Health Service on industrial hygiene will hold its first meeting early in the fall, Dr. W. Palmer Dearing, Acting Surgeon General of the Public Health Service, announced. The committee members will bring together the viewpoints of management, labor, the health professions and State health and labor departments. "This committee has long been needed," Dr. Dearing said. "Especially now, with the importance of the field of air pollution in industrial communities and the increasing interest of labor unions in health and welfare plans, is the Division of Industrial Hygiene in need of broad policy guidance from national leaders in the field." Members of the committee are: Andrew Fletcher, president, St. Joseph Lead Company, New York; Vincent P. Ahearn, of the National Sand and Gravel Association, Washington, D. C.; Nelson H. Cruikshank, of the American Federation of Labor; Harry Read, of the Congress of Industrial Organizations; Theodore F. Hatch, research director, Industrial Hygiene Foundation, Pittsburgh; Dr. R. H. Hutcheson, Commissioner of Public Health for the State of Tennessee, and Harold A. Vonachen, medical director of the Caterpillar Tractor Company, Peoria, Ill.

## TSETSE FLY AND MOSQUITO CONTROL

Dr. Frederick J. Brady, Assistant Chief, Laboratory of Tropical Diseases, National Institutes of Health, has been detailed to the Economic Cooperation Administration to make a preliminary survey of control of trypanosomiasis and malaria in British East and West Africa. Dr. Brady is now in Nigeria with Mr. Harry H. Stage, insecticide expert of the U. S. Department of Agriculture. After an investigation there of research programs, they will develop detailed recommendations for further U. S. assistance for control of the tsetse fly and mosquito in British dependent territories.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## ALABAMA

**Traveling Classroom for Physicians.**—The University of Alabama College of Medicine, University, has started its Traveling Seminar, a classroom on wheels for practicing physicians. Teams of doctors from the medical college conduct two and three day meetings throughout the state. The purpose is to keep the general practitioner abreast of medical progress. The Alabama State Medical Association is providing funds to pay for incidental expenses incurred by the lecturers. The Extension Division of the University of Alabama has taken on the responsibility of handling the mechanics of the meetings. Programs are in the hands of the seminar committee, composed of Drs. Robert F. Guthrie; Roy R. Kracke, dean of the school; Ray O. Noojin, and Roger D. Baker.

## ARIZONA

**Organize Rheumatism Society.**—A group of doctors especially interested in arthritis, rheumatism and allied disorders have formed a statewide society which will seek affiliation with the American Rheumatism Society. The group elected Dr. Harry E. Thompson, Tucson, president, and Dr. Alexander N. Shoun, Tuscson, secretary-treasurer. Occasional scientific programs will be conducted in Tucson and Phoenix and possibly in other localities to bring to physicians the newer developments in the treatment of rheumatic diseases.

## CALIFORNIA

**State Medical Election.**—The California Medical Association has chosen the following officers: Drs. R. Stanley Kneeshaw, San Jose, president; Donald Cass, Los Angeles, president-elect, and L. Henry Garland, San Francisco, secretary-treasurer.

**Physicians Aid Fund.**—The San Diego County Physicians Aid Fund has been activated for the use of members of the society to aid them financially in case of disability due to injury or illness. It will be under the direction of a three man committee appointed by the president of the society. Allotments from the fund are to be made available as a loan with no time limit clause and without interest. The fund is to be raised on a voluntary basis.

**How to Obtain a Family Doctor.**—The San Diego County Medical Society has approved a plan whereby all new residents in San Diego will be informed that those who do not have a family physician may obtain such services at any time through the Doctors Service Bureau. Newcomers will be contacted by the New Resident Service, which contacts personally an average of 500 new residents per month and mails their information to another 350 to 400 newcomers who cannot be reached in person.

## CONNECTICUT

**Auxiliary Distributes Pamphlets.**—Members of the Woman's Auxiliary of New Haven County distributed more than 40,000 educational pamphlets to 291 physicians' offices in a recent three day campaign. The distribution was in charge of Mrs. Alexander Bassin, New Haven, chairman of the auxiliary's Volunteer Committee. Space for sorting and wrapping literature was furnished by the New Haven Medical Association in its building at 364 Whitney Avenue. The communities on the distribution list included New Haven, East Haven, West Haven, Milford, North Haven, Hamden and Cheshire.

## KANSAS

**Outbreak of Food Poisoning.**—The Kansas State Board of Health reports that potato salad was responsible for the outbreak of food poisoning among 250 Seymour packing plant employees at the annual picnic in Topeka June 13. Hemolytic staphylococci were cultured from wounds on the hands of the person who prepared the salad in a private residence. Over 240 of the victims were hospitalized.

## KENTUCKY

**Poliomyelitis Centers.**—As part of the program being prepared by the Kentucky Poliomyelitis Planning Committee in conjunction with various health, hospital and medical agencies to combat the next poliomyelitis epidemic, centers are being established at Ashland, Somerset, Middlesboro and Bowling Green in addition to those already in operation at Louisville, Lexington, Paducah, Owensboro and Covington.

**McDowell House Open to the Public.**—The home of Dr. Ephriam McDowell, Danville's celebrated surgeon who performed the first ovariotomy in 1809, will be kept open to the public during June, July, August and September, from 10 a. m. to 5 p. m. on week days and from 2 p. m. to 5 p. m. on Sundays. This historic house at 125 South Second Street is being kept open by the Woman's Auxiliary of the Kentucky State Medical Association and a group of Danville women working in conjunction with the auxiliary. Hostesses will be in attendance each day to explain the historical background of the McDowell home.

**Appoint Director of Cancer Clinics.**—Dr. Robert H. English on July 1 became clinical director of Kentucky's cancer-mobile and eighteen cancer clinics sponsored by the state health department and the Kentucky Chapter of the American Cancer Society. During World War II he was stationed in Kentucky as an officer of the U. S. Public Health Service. During a recent three year residency in surgery at the U. S. Marine Hospital in Baltimore, he took special training in cancer surgery at the National Cancer Institute at Bethesda, Md. While on this assignment he was also a member of the faculty of Johns Hopkins University School of Medicine, Baltimore.

## LOUISIANA

**New President of State Board of Health.**—Dr. Stonewall J. Phillips of Thibodaux on July 1 succeeded Dr. William V. Garnier of Bastrop as president of the state board of health. Dr. Phillips has been assistant to Dr. Garnier. Dr. Phillips, a graduate of Tulane University of Louisiana School of Medicine, New Orleans, 1921, served with the state health department before entering the armed services in World War II. He worked with the North Carolina State Board of Health following the war and in August 1948 was named assistant to Dr. Garnier, who is retiring to take up private practice.

## MASSACHUSETTS

**Industrial Health Postgraduate Program.**—A new type of postgraduate program for training in industrial health will begin at Harvard University, Boston, in September. The program includes courses in planning, organizing and directing health efforts of industrial companies, whole industries, groups of companies and employees and will be under the direction of the department of industrial hygiene of the School of Public Health. The related teaching and research facilities of Harvard University, including certain special facilities at the Massachusetts Institute of Technology and other cooperating institutions, will be available. Philip Drinker, LL.D., is head of the department. The program will be divided into three major fields: industrial medicine, environmental hygiene and public health. Successful candidates will be awarded the newly established degree of Master of Industrial Health. The courses will be open to all qualified physicians, but preference will be given to persons who have had experience in industrial medicine. Those who wish to enroll either as candidates for the Master of Industrial Health degree or as special postgraduate students in the field of industrial health should apply to the secretary, Harvard School of Public Health, 55 Shattuck Street, Boston 15.

## MINNESOTA

**New Undergraduate Scholarships.**—Beginning next fall, a new program of scholarships will be offered to undergraduate students in the School of Medicine at the University of Minnesota by the Minnesota Medical Foundation. The scholarships will be awarded annually by the foundation in amounts totalling $2,500. Individual grants will range between $500 and $1,000. Students who will be members of the sophomore, junior and senior classes in the fall are eligible to apply, and application will be open from July 15 to September 1 for the coming school year. The scholarship program was authorized at a meeting of the board of directors, and Dr. Wesley W. Spink, professor of medicine at the university, was named chairman of a committee to draw up plans. Scholastic standing and financial need will be considered in the awarding of the scholarships. "There has long been a great need for undergraduate scholarships. Many students have to take part time jobs outside of school and it has been difficult for them to devote the amount of time needed to their medical studies," Dr. Spink said. Other members of the committee which drafted the program were Dr. Howard L. Horns, assistant dean of the medical school, and Dr. George N. Aagaard, director of postgraduate medical education at the university and secretary-treasurer of the foundation.

## NEW YORK

**University Appointment.**—Wallace O. Fenn, Ph.D., professor and chairman of the physiology department of the University of Rochester School of Medicine and Dentistry, was recently appointed assistant dean of the school. Dr. Fenn has been on the medical school faculty for 25 years.

**Cardiovascular Disease Project.**—The State Charities Aid Association has made an agreement with the American Heart Association to undertake a joint demonstration project on cardiovascular disease in the state exclusive of New York City. It is agreed that the program in the cardiovascular disease field shall be in accordance with standards and criteria established by the American Heart Association and with the acceptance of the program guidance of the American Heart Association staff; also that for an experimental period fund-raising activities would become the responsibility of the two committees of the local associations and that funds raised would be distributed in accordance with the current policies of the American Heart Association and the National Tuberculosis Association.

## TENNESSEE

**Portrait of Dr. McGehee.**—A portrait of the late Dr. J. Lucius McGehee, for 46 years a member of the faculty of the university and for the last 15 years head of the department of surgery, was presented to the university at commencement exercises on June 13. Dr. McGehee died Feb. 16, 1949. The portrait was presented by those who had served residencies under his direction.

**New Assistant Dean.**—Dr. Robert H. Miller, Memphis, associated with the University of Tennessee since 1914, retired June 30 as assistant dean of medicine and was succeeded by Dr. Frank L. Roberts, professor of preventive medicine. Dr. Miller taught in the department of anatomy beginning in 1914, was made a full time associate professor in anatomy in 1924 and had been assistant dean since 1939. Dr. Roberts received his M.D. degree from the University of Minnesota Medical School, Minneapolis, in 1922. Before joining the university as professor and head of the department of preventive medicine, he had been health officer of Gibson County for twelve years.

## TEXAS

**Personal.**—Dr. Frank M. Townsend of the Scott and White Clinic, Temple, has accepted appointment as associate professor of surgical pathology at the University of Texas School of Medicine, Galveston, beginning in October. Dr. Townsend will also be consulting surgical pathologist to the hospitals of the University of Texas Medical Branch.

**State Medical Election.**—Officers of the State Medical Association of Texas for the coming year include Drs. George V. Brindley, Temple, president; William M. Gambrell, Austin, president-elect; Thomas H. Thomason, Fort Worth, treasurer, and Harold M. Williams, Fort Worth, secretary-editor. Delegates to the American Medical Association with terms beginning in January 1950 are Drs. Truman C. Terrell, Fort Worth; Edward H. Cary, Dallas, and Britton E. Pickett Sr., Carrizo Springs.

**Laboratory for Industrial Hygiene.**—The University of Texas Medical Branch, Galveston, plans to open a special research laboratory for industrial hygiene in September. Facilities and space have been provided for the project, which will be under the direction of Dr. Carl A. Nau, professor of preventive medicine and public health, and J. M. Neal, sanitary engineer. The new laboratory will cooperate particularly with the heavy industries in Texas City, but is available for consultation and service to all Texas industries.

## VERMONT

**State Society Appoints Executive Secretary.**—The Vermont State Medical Society announces the appointment of Mr. Getty Page as executive secretary and public relations director. A graduate of Syracuse University, he has served as American Red Cross field director and state relations officer; more recently he has been dean of students, professor of biology and director of health and physical education at Rutland Junior College.

**Open Cardiovascular Unit.**—The Cardiovascular Unit at the Bishop DeGoesbriand Hospital was established by the College of Medicine of the University of Vermont for the special study and care of cardiovascular patients by means of modern scientific methods. It went into operation July 1. Investigative work now in progress is partly supported by funds from the National Heart Institute and the American Heart Association. A cardiovascular outpatient clinic, conducted by Dr. Christopher M. Terrien, will function in close cooperation with the unit. The cardiovascular unit will continue its refresher course on cardiovascular diseases for general practitioners in Northern New England and vicinity. A course of 28 lectures was given June 13-18.

## WISCONSIN

**Dr. Elvehjem Receives Nutrition Award.**—Conrad A. Elvehjem, Ph.D., of the University of Wisconsin, Madison, was honored at the recent annual meeting of the National Live Stock and Meat Board. He was presented an award in recognition of his contribution to the science of biochemistry in the field of nutrition. The board has placed several research grants at the University of Wisconsin in support of studies which have been carried on under the direction of Dr. Elvehjem.

**Mental Hospitals Included in Preceptorship Program.**—University of Wisconsin Medical School fourth year medical students began study June 27 in state mental hospitals as part of their preceptorship training. The program will give students an opportunity to view first hand the treatment of mental illness and will augment their academic training with practical application. Under Wisconsin's preceptorship system, which has been carried on for years by the medical school, senior medical students spend half their time at the university working in the State of Wisconsin General Hospital, Madison, and the other half at medical centers in the state. About half of the latter time is spent in small communities working under an established doctor.

## GENERAL

**International College of Surgeons.**—The annual assembly of the United States Chapter of the International College of Surgeons will be held at Haddon Hall in Atlantic City November 8-11. On November 7 surgical clinics will be held in the leading Philadelphia hospitals.

**Ambulatory Fracture Association Meeting.**—The annual meeting of the Ambulatory Fracture Association will be held October 24-27 at the Royal York Hotel, Toronto, Canada, under the presidency of Dr. Custis L. Hall, Washington, D. C. Scientific papers, roundtable discussions and operative clinics are included in the program.

**Award Putnam Fellowship.**—Mrs. Molly M. Jones, Ph.D., Claremont, Calif., has been awarded the $2,600 Helen Putnam Fellowship for advanced research in genetics and mental health by Radcliffe College, Cambridge, Mass., for preparation of a book on the learning process in children and problems in their guidance. Mrs. Jones is director of the Mary B. Eyre Nursery School and associate professor of psychology.

**Mental Health Bulletin.**—The first *Bulletin of the World Federation for Mental Health* was published in February. The bulletin is to be published every two months at 5 shillings ($1) per year, post free, by the federation, 19 Manchester Street, London, W.1. It is the successor to the series of 12 bulletins distributed by the International Congress on Mental Health held in London in August 1948. The World Federation for Mental Health was organized in August 1948 with the founder members from 21 countries (THE JOURNAL, Dec. 4, 1948).

**Congress on Physical Medicine.**—The American Congress of Physical Medicine will hold its annual session September 6-10 at the Netherland Plaza Hotel, Cincinnati. All sessions will be open to members of the medical profession in good standing with the American Medical Association. The annual instruction courses will be held September 6-9 in two groups: One set of ten lectures will consist of basic subjects, and attendance will be limited to physicians; one set of ten lectures will be more general in character. Information may be obtained from the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2, Ill.

**Occupational Therapy Meeting.**—The American Occupational Therapy Association will hold its annual convention August 20-27 at the Book-Cadillac Hotel, Detroit. The general theme of the convention will be "Dynamic Forces in Occupational Therapy." Several symposiums are scheduled for Wednesday and Thursday: Wheels of Progress in Rheumatic Fever; Machinery for the Rehabilitation of the Tuberculous; Assembling Forces for the Cerebral Palsied Child; More Power for

Multiple Sclerosis; The Rehabilitation Center; Chest Surgery; Mobilizing Occupational Therapists; Epileptic Panel, and Psychodynamics of Primary Behavior Disorders of Children. The speaker at the banquet Wednesday at 7 p. m. will be Dr. Orus R. Yoder, Ypsilanti, "Blue Prints for the Future."

**"Spanish Swindle" Letters.**—According to the Post Office Department, addresses are being selected from lists of professional persons as recipients of the so-called "Spanish Swindle" letters. Ordinarily, reply to the first letter will bring a three page letter, with fake newspaper clippings and legal papers, intended to substantiate the writer's story concerning his imprisonment and arranging for the victim's arrival in Mexico, whereupon he is relieved of his funds by trickery or violence. Fraud orders are issued against these swindlers as the various names they use are reported to the Post Office Department. Such orders prohibit the dispatch of mail to the persons named and also prohibit the certification of payment of postal money orders drawn in their favor.

**Prevalence of Poliomyelitis.**—Reports of cases of poliomyelitis for the periods indicated have been received from the Division of Public Health Methods, U. S. Public Health Service:

* Last two columns show reported incidence since approximate average seasonal low week: 16 weeks.

† Figures changed by corrected reports.

**Special Society Elections.**—The American Psychiatric Association at its recent meeting installed Dr. George S. Stevenson, New York, as president and chose Dr. John C. Whitehorn, Baltimore, president-elect. Drs. Leo H. Bartemeier, Detroit, and Howard W. Potter, Brooklyn, were reelected secretary and treasurer, respectively.——The American Society for the Study of Arteriosclerosis has selected as officers for the coming year Drs. Irvine H. Page, Cleveland, president, and Otakar J. Pollak, Quincy, Mass., secretary-treasurer. The next annual meeting of the society will be held November 5-7 at the Knickerbocker, Chicago.——The American Neurological Association at its meeting in Atlantic City June 13-15 chose Dr. Henry W. Woltman, Rochester, Minn., president and Dr. H. Houston Merritt, New York, secretary-treasurer.

**Ernest Little to Receive Remington Medal.**—Ernest Little, Ph.D., Newark, N. J., past president of the American Pharmaceutical Association, professor of chemistry and former dean of Rutgers University College of Pharmacy, New Brunswick, N. J., has been named the twenty-seventh Remington Medalist. The medal will be conferred "in recognition of his tireless efforts on behalf of pharmaceutical education, for his sane and intelligent attitude toward pharmacy in all its subdivisions, for his excellent handling of students, for his work in establishing American Pharmaceutical Association student branches, and for his great interest in the general welfare of pharmacy." The Remington Medal Award is made by the New York Branch of the American Pharmaceutical Association. The presentation ceremonies will be held in New York City this fall. The gold medal is given in commemoration of Joseph P. Remington, who was chairman of the Pharmacopeia of the United States Revision Committee for several decades. Dr. Little was president of the American Foundation for Pharmaceutical Education for two years and is now a member of its Board of Grants. For several years Dr. Little was a member of the American Council on Pharmaceutical Education and served one term as vice president of that group. From 1930 to 1940 he was a member of the U. S. P. Revision Committee Since that time he has been a member of the U. S. P. Board of Trustees.

## LATIN AMERICA

**Congress of Anaesthesiology.** — The Second Argentina Congress and the First Latin American Congress of Anaesthesiology will take place in Buenos Aires, Argentina, October 16-23. One outstanding anesthetist from the United States, Canada and each of the most important Latin American countries will be invited to speak. The program arranged thus far includes Dr. R. Owen Elder, Buenos Aires, "Spinal Anesthesia," and Dr. Roberto A. Goyenechia, Buenos Aires, "Anesthesia in Surgery of the Chest." The Association of Anaesthesiology in Argentina is arranging the congress; the secretary is Dr. Italo Nunziata, Sarmiento 2135, 4° P. H., Buenos Aires.

**Argentina Congress on Obstetrics and Gynecology.**—The Seventh Argentine Congress of Obstetrics and Gynecology will be held October 23-29 at the Faculty of Medicine of Buenos Aires, J. E. Uriburu 955. The congress was organized by the Society of Obstetrics and Gynecology of Buenos Aires. Official speakers include the following:

J. Pereira and J. Baxán, Syphilis in Maternity Hospitals.
R. García Valenzuela and C. J. Duverges, Control and Management of Delivery.
V. Rodriguez and N. Arenas, Carcinoma of Endometrium.
J. J. Crottogini and J. L. Sardi, Genital Tuberculosis.

There will be an exhibit on obstetric and gynecologic subjects. The quota for titular members is 50 Argentinean pesos ($12) and for temporary members 30 pesos ($8). Further information can be obtained from the general secretary, Dr. A. Peralta Ramos (H), Séptimo Congreso Argentino de Obstetricia y Ginecología, Santa Fe 1171, Buenos Aires, Argentina.

# Marriages

Howard E. Wiener, Cedarhurst, N. Y., to Miss Marilyn Fenton of New York, June 2.

Donald Wray Spratt to Miss Anne Garside, both of Rochester, N. Y., May 5.

Matthew E. Morrow to Miss Sara Marion Watson, both of Jacksonville, Fla., April 8.

Robert S. Cleaver, Brewster, N. Y., to Miss Alma A. Hall in Binghamton, April 30.

Shaler Richardson to Mrs. Nada Coffee Bailey, both of Jacksonville, Fla., May 7.

# Deaths

**William Gerry Morgan** ⊕ President of the American Medical Association, 1930-1931, died at his home in Washington, D. C., July 7, aged 81. Dr. Morgan was born in Newport, N. H., May 2, 1868. He received his A.B. degree from Dartmouth in 1890 and was awarded his medical degree by the University of Pennsylvania Department of Medicine, Philadelphia, in 1893. After postgraduate work he began practice in Southport, Conn., in 1894. In 1899 he moved to Washington, D. C., and joined the faculty of Georgetown University School of Medicine, serving for many years as professor of gastroenterology, member of the board of regents and as dean from 1931 to 1935, when he retired with the title of dean emeritus.

Dr. Morgan was a member of the House of Delegates of the American Medical Association from 1920 to 1926, a past president of the Medical Society of the District of Columbia, American Congress of Internal Medicine, American Gastro-Enterological Association and the Clinico-Pathological Society. He was a councilor of the Southern Medical Association, a fellow, master, formerly a regent, governor, secretary-treasurer and vice president of the American College of Physicians. He was a member of the New York Academy of Medicine, Washington Academy of Sciences, of which he was vice president in 1919, the Association of Military Surgeons of the United States and the American Association of the History of Medicine. He was an honorary member of the New Hampshire Medical Society. In 1922 and in 1924 he was a member of the U. S. Annual Assay Commission and in 1935 was a United States delegate to the International Gastro-Enterological Society in Brussels. Dr. Morgan was chairman of the advisory draft board during World War I and joined the Army Reserve Corps, from which he retired in 1932 with the rank of major. He was a specialist certified by the American Board of Internal Medicine and was a consulting physician at Garfield Memorial, Gallinger and Georgetown University hospitals. The honorary degree of doctor of laws was conferred on him by the University of Pennsylvania and Georgetown University. Dr. Morgan was the author of "American College of Physicians: Its First Quarter Century" and "The Gastrointestinal Tract."

William Gerry Morgan, M.D.

**Benjamin Milton Cissel** ⊕ Brooklyn; born in Highland, Md., in 1893; Johns Hopkins University School of Medicine, Baltimore, 1919; instructor from 1924 to 1927, associate in 1927 and 1928, assistant clinical professor of surgery from 1928 to 1930, assistant clinical professor from 1930 to 1947, when he became associate professor of clinical surgery at the Long Island College of Medicine; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons and the New York Academy of Medicine; affiliated with the Swedish, King's County and Long Island College hospitals; died May 31, aged 56.

**Sydney Robotham Miller** ⊕ Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1910; an Associate Fellow of the American Medical Association; formerly on the faculty of the University of Maryland School of Medicine; specialist certified by the American Board of Internal Medicine; fellow and past president of the American College of Physicians; past president of the American Congress of Internal Medicine; member of the American Clinical and Climatological Association; served during World War I; on the staffs of the Union Memorial Hospital and the Hospital for the Women of Maryland; died May 25, aged 65.

**Edson Moses Abbott,** Rochester, N. H.; University of Vermont College of Medicine, Burlington, 1898; member of the American Medical Association; died in Frisbie Memorial Hospital May 14, aged 80.

**Franklin William Barrows** ⊕ Dumont, N. J.; University of Buffalo School of Medicine, 1893; member of Medical Society of the State of New York; at one time a member of the state department of education in Albany, N. Y., and school medical inspector at New Rochelle, N. Y.; a trustee of the Dixon Homestead Library; died May 25, aged 86, of lobar pneumonia.

**James Robert Bean,** Bend, Ore.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; member of the Idaho State Medical Association and the American Medical Association; formerly practiced in Wallace, Idaho, where he was secretary of the Shoshone County Medical Society, chairman of the school board, county health officer, city health officer and member of the staff of Providence Hospital; died in Portland April 14, aged 67.

**Corda Earl Beeman** ⊕ Grand Rapids, Mich.; Cleveland Homeopathic Medical College, 1903; fellow of the American College of Surgeons; on the staffs of Butterworth, St. Mary's and Blodgett Memorial hospitals, where he died May 9, aged 75, of benign hypertrophy of prostate and hypertension.

**Philip Leon Bereano,** New York; Eclectic Medical College of the City of New York, 1905; Long Island College Hospital, Brooklyn, 1909; served on the staffs of Morrisania City and Lebanon hospitals; founder and member of the medical staff of Jewish Home for Convalescents in Hudson, N. Y.; died in St. Luke's Hospital May 22, aged 70.

**Victor Joseph Blanchette,** Scottville, Mich.; Chicago College of Medicine and Surgery, 1907; member of the American Medical Association; died in Gerber Memorial Hospital in Fremont, May 4, aged 62.

**Byron H. Boone,** Acton, Ind.; Kentucky School of Medicine, Louisville, 1894; died May 19, aged 83, of carcinoma of the prostate.

**Jacob Byer,** New York; University of Maryland School of Medicine and College of Physicians and Surgeons, 1932; member of the American Medical Association; specialist certified by the American Board of Physical Medicine; served during World War II; formerly on the staffs of Veterans Administration hospitals in Legion, Texas, and Whipple, Ariz.; died May 7, aged 43.

**Joseph Rodwell Carver,** Dalton, Ga.; University of Georgia School of Medicine, Augusta, 1947; member of the American Medical Association; drowned in the Suwannee River at Branford, Fla., April 19, aged 30, when the boat in which he was cruising capsized.

**Edwin Crosby Chamberlin,** Brewster, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1894; died in the Milford (Del.) Hospital May 21, aged 79.

**Hugh W. Chaney,** Sugar Tree Ridge, Ohio; Hospital College of Medicine, Louisville, Ky., 1903; member of the American Medical Association; died in Highland Community Hospital, Hillsboro, May 3, aged 78, of cerebral hemorrhage.

**Ivra Allen Clark,** Camden, Ark.; Meharry Medical College, Nashville, Tenn., 1914; died in the Mayo Clinic, Rochester, Minn., May 5, aged 66, of uremia and hypertrophy of the prostate.

**Frank Jennings Cornelius** ⊕ Olympia, Wash.; State University of Iowa College of Medicine, Iowa City, 1923; served during World Wars I and II; affiliated with St. Peter's Hospital, where he died April 21, aged 49, of cerebral embolus.

**James Gardner Culpepper,** Moultrie, Ga.; University of Georgia Medical Department, Augusta, 1891; for many years served as county physician; died March 31, aged 80.

**Martin Dominic Currigan** ⊕ Denver; University of Colorado School of Medicine, Denver, 1912; fellow of the American College of Surgeons; at one time regent at his alma mater; on the staff of St. Joseph's Hospital, where he died May 12, aged 61, of dissecting aneurysm of the ascending aorta with rupture into pericardium.

**Medus Monroe Davis**, Indiana, Pa.; Jefferson Medical College of Philadelphia, 1893; member of the American Medical Association; served during World War I; formerly county coroner; died May 9, aged 81, of coronary thrombosis.

**John MacArthur Dunsmore**, Barrington, R. I.; Trinity Medical College, Toronto, Ont., Canada, 1898; member of the Missouri State Medical Association and the American Medical Association; specialist certified by the American Board of Psychiatry and Neurology, Inc.; died in Providence May 16, aged 78, of fracture of a lumbar vertebra received when he slipped in the bathtub.

**William Henry Elliott**, Bunceton, Mo.; Barnes Medical College, St. Louis, 1899; served as a member and president of the local school board; died May 27, aged 73, of a ruptured spleen following a fall.

**Charles H. Fairbanks**, Grand Rapids, Mich.; Grand Rapids Medical College, 1899; served on the staff of Blodgett Memorial Hospital; died May 2, aged 89, of chronic arteriosclerotic myocarditis.

**Tom Keller Farnsworth**, Long Beach, Calif.; State University of Iowa College of Medicine, Iowa City, 1924; on the staff of Community Hospital; died April 16, aged 48, of heart disease.

**William S. Green**, Ridgewood, N. J.; University of the City of New York Medical Department, New York, 1887; formerly practiced in Paterson, where he was for many years associated with the board of health; died in St. Joseph's Hospital, Paterson, June 2, aged 87.

**Washington G. Hammond**, Telephone, Texas (licensed in Texas under the Act of 1907); died May 8, aged 80.

**Alfred Paul Hancuff** ⊕ Toledo, Ohio; Ohio State University College of Medicine, Columbus, 1917; fellow of the American College of Surgeons; served as president, secretary and member of the council of the Academy of Medicine of Toledo and Lucas County; affiliated with Mercy, Maumee Valley, St. Vincent's and Lucas County hospitals; died May 9, aged 56, of coronary occlusion.

**George Blight Harrison** ⊕ Fredericksburg, Va.; University of Maryland School of Medicine, Baltimore, 1905; past president of the Northern Neck Medical Association; served during World War I; affiliated with Mary Washington Hospital; died May 17, aged 68, of coronary thrombosis.

**John Henry Hartnett** ⊕ Worcester, Mass.; Tufts College Medical School, Boston, 1911; served as a member of the board of health; affiliated with Belmont Hospital and St. Vincent Hospital, where he died May 10, aged 73, of cerebral hemorrhage.

**Herbert Hodge Haynes** ⊕ Clarksburg, W. Va.; College of Physicians and Surgeons, Baltimore, 1908; served as vice president of the West Virginia State Medical Association; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; served during World War I; on the staff of St. Mary's Hospital, where he died June 2, aged 71, of coronary occlusion.

**Johnson Washington Hill**, Boston; College of Physicians and Surgeons, Boston, 1908; died May 12, aged 74.

**Elizabeth M. Hocker**, Cincinnati; Laura Memorial Woman's Medical College, Cincinnati, 1897; served overseas during World War I as an anesthetist in an Army hospital unit; for many years on the staff of Christ Hospital; died May 22.

**John Woodford Holloway** ⊕ Cleveland; Western Reserve University School of Medicine, Cleveland, 1923; assistant clinical professor of surgery at his alma mater; fellow of the American College of Surgeons; on the staff of Lakeside Hospital; died June 2, aged 53, of cerebral hemorrhage and hypertensive cardiovascular disease.

**Lloyd William Johnson** ⊕ Pittsburgh; University of Pennsylvania School of Medicine, Philadelphia, 1913; fellow of the American College of Surgeons; on the staff of Allegheny General Hospital; died June 6, aged 62, of cardiac failure.

**William Elijah Johnson**, Altadena, Calif.; University of Colorado School of Medicine, Denver, 1913; fellow of the American College of Surgeons; died in Beverly Hospital, Montebello, April 7, aged 60, of coronary thrombosis.

**Corban Eaton Judd**, San Jose, Calif.; Rush Medical College, Chicago, 1898; formerly practiced in Topeka, Kan., where he was secretary of the Shawnee County Medical Society and was on the staff of Stormont Hospital; died April 20, aged 73, of cerebral hemorrhage.

**Ernest Kohn**, Grover Hill, Ohio; Fort Wayne College of Medicine, 1894; member of the American Medical Association; member of the county board of health; died May 10, aged 78, of carcinoma.

**Homer Jonas Rhode** ⊕ Reading, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1901; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; specialist certified by the American Board of Ophthalmology; served on the staffs of Reading and St. Joseph's hospitals; died in Miami, Fla., June 3, aged 71, of coronary thrombosis and diabetes mellitus.

**Sterling Ruffin** ⊕ Washington, D. C.; Columbian University Medical Department, Washington, 1890; professor of medicine at his alma mater, now known as George Washington University School of Medicine, for many years and later became professor emeritus; past president of the Medical Society of District of Columbia; member of the American Clinical and Climatological Association; senior director of Riggs National Bank; on the staffs of Garfield Hospital and George Washington University Hospital, where he died May 31, aged 82, of cerebral thrombosis.

**Philip Hamblin Smith** ⊕ Evanston, Ill.; Northwestern University Medical School, Chicago, 1927; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; associate in obstetrics and gynecology at his alma mater; specialist certified by the American Board of Obstetrics and Gynecologists; on the staff of Evanston Hospital; died May 24, aged 49.

**William Henry Specht**, Germantown, N. Y.; Cornell University Medical College, New York, 1906; formerly on the staff of the Park East Hospital in New York; died while on a fishing trip in Canada, May 19, aged 67.

**Anne Heath Thomas** ⊕ Colorado Springs, Colo.; Woman's Medical College of Pennsylvania, Philadelphia, 1905; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; formerly on the faculty of her alma mater; died in the Glockner Hospital May 21, aged 76, of diverticulitis of the sigmoid with perforation.

**Joseph Browning Thornell** ⊕ Council Bluffs, Iowa; University of Nebraska College of Medicine, Omaha, 1927; served during World War I; affiliated with Jennie Edmundson Memorial Hospital; died May 20, aged 60, of carcinoma.

**James William Thornton**, Sacramento, Calif.; John A. Creighton Medical College, Omaha, 1899; served during the Spanish-American War and World War I; formerly affiliated with the U. S. Public Health Service, reserve, and on the staffs of various Veterans Administration hospitals; died May 14, aged 74.

**Charles Todd**, Glen Arbor, Mich.; Northwestern University Medical School, Chicago, 1896; died in Traverse City April 26, aged 79, of chronic peptic ulcer, with hemorrhage.

**May Gibson Waters**, Hamlet, N. Y.; University of Buffalo School of Medicine, 1903; died April 15, aged 79, of metastatic carcinoma.

**William J. Whitefort** ⊕ St. Elmo, Ill.; Missouri Medical College, St. Louis, 1898; served during World War I; died May 22, aged 74, of chronic myocardial insufficiency.

**Paul Vintcent Woolley**, Excelsior Springs, Mo.; University Medical College of Kansas City, 1905; formerly police surgeon in Kansas City; served during World War I; died in the U. S. Naval Hospital in Corona, Calif., May 4, aged 68, of carcinoma of the left lung.

**Dee D. Worden**, Louisville, Ky.; Kentucky University Medical Department, Louisville, 1906; member of the American Medical Association; on the staff of St. Joseph Infirmary; on the courtesy staffs of the Kentucky Baptist and Jewish hospitals; died April 28, aged 68, of cirrhosis of the liver.

**Hubert Lee Wyatt**, China Grove, N. C.; Medical College of Virginia, Richmond, 1916; member of the American Medical Association; served during World War I; died in the Rowan Memorial Hospital, Salisbury, May 2, aged 58, of coronary thrombosis.

**August Karl Zinn**, Ypsilanti, Mich.; University of Michigan Medical School, Ann Arbor, 1925; member of the American Medical Association; served during World War II; affiliated with the Beyer Memorial Hospital, where he died May 15, aged 47, of carcinoma of the cecum.

## BELGIUM

*(From Our Regular Correspondent)*

June 16, 1949.

### Coordination of International Medical Conventions

The first assembly of the permanent Council for the Coordination of the International Conventions of Medical Sciences will be held in Belgium. It is the result of numerous discussions held by international scientific societies to formulate the fundamental principles on which this new organization is to be founded.

UNESCO took the initiative at the first meeting, which was held in 1947, and called a preparatory conference of presidents and delegates of the seventeenth International Congress of Medical Sciences, which at this time had resumed its activity. Today the aim of the combined efforts of O. M. S. (Organization of Medical Sciences) and UNESCO is different. It is no longer a question of trying to fuse but to coordinate the work of different specialties, which work in very diverse ways and at the same time are to aid and sustain the respective international organizations.

The committee of organization of the permanent Council for the Coordination of the International Congress of Medical Sciences considers it necessary: (1) to coordinate the international congress with respect to the choice of dates, locations and special subjects of common interest; (2) to keep informed about all conventions, conferences and reunions organized by the international scientific unions which concern related sciences and coordinate them with the reunions concerned with medical sciences; (3) to concern itself with all problems presented by the material and technical organization of conventions, and (4) to serve as a channel for the material aid which UNESCO and O. M. S. can supply to reunions and to the international congresses with the aim to facilitate their meetings and to permit their members and the invited specialists to take part therein.

The future council will have: (1) the task of information (place, date, subjects, and reporters of congresses) and establishment of agendas; (2) the task of material financial and technical aid; (3) the task of diffusion (editions, translations and reports) and (4) the task of favoring certain orientations. Under this last item are (*a*) symposiums—small conferences in which scientists of various disciplines study a subject with the aim of going deeper into a problem and opening up new horizons for investigators; (*b*) orientation of efforts with the view of improving the technics in studying different technics at the same time and in the same place; (*c*) participation of those who attend a congress in the medical life of the country in which the congress is held and reciprocal postgraduate instructions, and (*d*) information to the general public, not by the old and mediocre methods of popularization, but by a sane cultural education.

A large part of the efforts of the assembly was devoted to the elaboration and the acceptance (subject to the approbation of the participating organization) of the statutes and regulations of the interior order of the new World Council. The location of the next general assembly has been designated by the assembly. It will be in Geneva in 1952.

### Cancerigenic Substances

At the medical meeting of the Society of Stomatology, Professor Maisin presented a summary of the knowledge of the cancerigenic agents. He subdivided them into cancerigenic agents of known chemical composition, among which there are the hydrocarbon derivatives of anthracene, benzopyrine, cholanthrene and phenanthrene.

It is remarkable that small differences in the structural position of a group permits one to obtain a cancerigenic substance or a substance which does not have this characteristic.

There are also cancerigenic nitrogen compounds, for example, the derivatives of carbazole, and, in this respect, such substances as butter yellow, which is utilized in the food industries and produces cancers of the liver, as well as other anilines, such as amber yellow, which is utilized for coloring oils, and even the light greens have been recognized as being cancerigenic, when injected subcutaneously.

Aside from these numerous substances, there are others of unknown formulas, such as the products of various substances present in the liver and even the products of the combustion of meats; this suggests that one can perhaps ingest cancerigenic substances. Aside from these compounds with more or less complex formulas, there exist simple substances, such as the metals: chromium, cobalt and metallic arsenic.

Finally, he discusses the role of hormones, especially female hormones, in the genesis of cancer of the breast.

### Number of Physicians

The report of the University Foundation for 1948 has provided some interesting figures. In the four Belgian universities, 1,038 students were registered for the first year medical course during the present year. In the second year the total number was 646. For the third year the total was 603. Thus the great reduction takes place after the first year; this can be explained easily. The population of the subsequent years (there are seven years of study) present fluctuations that are doubtlessly due to the war. In the fourth year the total was 498 students; in the fifth year 292 students; in the sixth year 374 students, and in the seventh year 385 students.

The discussion published in the *Scalpel*, the oldest medical journal of Belgium, comments on these facts as follows: It would appear that in two years the figure will increase approximately 25 per cent and one can foresee that in three years nearly 500 new physicians will come out of the medical faculties.

With this outlook it will be necessary to give serious thought to the rational organization of the profession and take account of the openings which may be offered in the services in the Congo, the extension of the health services and the progress in the organization of hospitals.

### Colonial Medical Center

To guarantee the objective recruiting and the medical supervision of personnel sent to the colonies, the Colonial Medical Center, created in 1948, has modified its regulations. The present colonial organization bearing the title Colonial Medical Center performs all examinations with a view to establishing suitableness for life in the colony or to determine whether the person has the physical condition required of employees of the colony, proceeds with the detection and treatment of disorders resulting from living in the tropical regions, gives medical care to the personnel of the colonial administration and keeps up to date the medical records on the personnel of the colonial administration.

### International Art Exhibit of Physicians

Since the liberation we have had an exhibit of paintings and sculpture for the fourth time. This has almost become a national event in our country, in which the history of the fine arts is closely allied to the life of the nation.

This year the art exhibit, which has taken an important place in the artistic movement, was held at the grand Palais at Liège. This fourth exhibit represents considerable progress over the preceding ones, and the critics have been unanimous in drawing attention to the incomparable work of Dr. Vandervael, who is considered a painter of great talent.

## LATE RADIATION EFFECTS IN ROENTGEN THERAPY FOR HYPERTHYROIDISM

### Their Possible Bearing on the Use of Radioactive Iodine

*To the Editor:*—Radioactive iodine, especially the isotope of 8 day half-life, $I^{131}$, has been employed in the treatment of hyperthyroidism in several clinics during recent years, a total of several hundred patients probably having received the material. The question of the possibility of late radiation changes leading to malignant degeneration has been raised and cannot be disregarded. Serious sequelae to radiation therapy usually appear several years after the treatment; hence such damage from radioiodine would not be expected for some time. If it is to be feared that this will be a serious hazard, the use of the material ought to be very sharply restricted until sufficient time has elapsed to ascertain the late results in persons already treated. On the other hand, if any pertinent evidence can be obtained from the already large experience with roentgen rays, it should be made available.

With this in mind, a questionnaire was sent out to a group of radiologists and thyroid specialists who might have had long term experience in the treatment of toxic goiter with roentgen rays. The questions were as follows:

1. Have you ever seen a cancer arise in a thyroid gland, in a case of hyperthyroidism which had been previously treated with roentgen rays? If so, was the gland nodular?

2. Have you ever seen a cancer arise in adjacent structures in a case of hyperthyroidism previously treated with roentgen rays?

3. Have you ever seen a cancer arise in a normal thyroid gland, when that region had been in the field of roentgen ray treatments for another condition?

4. Have you ever seen a cancer of the thyroid develop in a patient who has undergone any treatment for hyperthyroidism other than radiation? If so was the gland nodular? If the answer to any of these questions is YES, please send a detailed case history.

Responses were received from 70 radiologists and 31 thyroid specialists; of these latter, 4 declared themselves unqualified to give information. A total of 71 (53 radiologists and 18 medical specialists) returned a categoric NO to all questions. Some of these volunteered that their experience was small; others stated that their series contained several hundred cases, followed over many years. The remaining 30 answered NO to most of the questions, but made some positive statements which should be analyzed in detail.

In answer to the first question, 10 cases were reported of cancer arising in thyroid glands in which roentgen rays had been previously given for hyperthyroidism. These merit individual consideration:

1. A young woman treated about 1920; no details were given.

2. A woman treated in 1916; extensive carcinoma of the thyroid in 1945.

3. Gland nodular; no further data were given.

4. A woman of 50; roentgen treatment for exophthalmic goiter; no details of dosage were given. Three or four years later death occurred from tracheal obstruction; at autopsy cancer of the thyroid was seen.

5. A man, of unknown age, treated in 1934 with six roentgen exposures for toxic adenoma. In 1938, inoperable cancer was discovered, but no skin changes from roentgen therapy.

6. A girl, 14 years old, received six or eight roentgen treatments for toxic goiter in 1918. In 1938, operation for what was thought to be advanced toxic goiter revealed cancer. No skin changes followed roentgen treatment.

7. A patient, 47 years old, had three or four roentgen treatments for toxic thyroid in 1923. In 1944, advanced adenocarcinoma was seen. No skin changes due to the roentgen rays were seen.

8. A young woman was treated in 1925-1926 with eleven exposures about three weeks apart, about 200 r to the thyroid each time. In 1945 carcinoma was discovered, but no skin changes due to roentgen rays.

9. A woman, 24 years old, was treated in 1921 for classic toxic diffuse goiter (Graves disease). The patient stated that she had had eighteen treatments at weekly intervals. In 1933, during her second pregnancy, symptoms of toxicity recurred; the gland was then thought to be nodular; at operation, carcinoma was found, but no skin changes due to roentgen rays.

10. A woman, 68 years old, was treated in 1937 for "swelling in the thyroid region." The patient stated that she had had 30 to 40 treatments over a two year period. Some skin changes in the irradiated areas were seen. In 1947 an anaplastic solid carcinoma of the thyroid was observed.

To summarize these 10 cases, no definite information is available about the first and second; in the third and fifth there were nodular glands, in which cancer is known to arise with some frequency. In the fourth and fifth cases cancer was found within three or four years, which is early for the development of radiation-induced cancer when dosage has not been excessive. In the fifth, sixth and seventh few treatments had been given; it is doubtful whether the doses were large enough to cause late damage. Thus the last 3 (8, 9, 10) are the only ones in which the history indicates even the possibility that roentgen rays were implicated in the production of the cancer. Only 1 of the 10 patients apparently showed any late skin changes due to the roentgen rays (although this has been observed in a considerable number of patients treated for hyperthyroidism in the 1920's). However, it cannot be definitely stated that the radiation had nothing to do with the development of a malignant condition in any of these persons.

In response to the second question, eight radiologists reported having seen cancer of the skin of the neck following roentgen treatment for hyperthyroidism; some of these stated that they had seen several cases. In addition, 2 cases of cancer of the larynx were reported, and 1 each of esophagus and trachea. Details of therapy are not available for the 2 in whom cancer of the larynx developed. The patients with cancer of the trachea and esophagus, women of 34 and 28 years, respectively, in 1925 and 1921, received fairly heavy irradiation for hyperthyroidism. Both later showed pronounced telangiectasia in the irradiated skin; their cancers developed about twenty years after the treatments had been given.

As to the third question, no one had seen cancer produced in a normal thyroid gland which fell within the field of irradiation for some other malignant condition, such as cancer of the larynx. Several radiologists in discussing this question stated that they must have irradiated many normal thyroids in this manner, with radiation doses far in excess of any employed in hyperthyroid therapy, that some of these patients had been under observation for a good many years (ten or more) and that they have never seen any effect on the gland.

In answer to question 4, nine physicians or radiologists had seen cancer arise in hyperthyroid glands treated otherwise than by irradiation. Both surgical and medical treatments were specified. Some cases were stated to have been of toxic nodular goiter, but 2 were stated to have been of primary hyperplastic, not nodular, goiter.

From this response of 101 radiologists and thyroid specialists to a questionnaire regarding the late malignant changes following roentgen treatment of hyperthyroidism, it is apparent that, if the complication exists, it is very rare. In applying the results of this survey to the use of radioactive iodine in the treatment of this disease, it must be realized that radiation doses from roentgen rays and from $I^{131}$ may be quite different. Externally administered roentgen rays bathe the gland with a fairly uniform radiation. Radioautographs show that radioactive iodine may be deposited in a very spotty manner, so that some regions receive much more radiation than others. A survey of modern roentgenologic technics indicates that a dose to the gland of about 3,000 to 3,500 r is considered adequate. However, it appears that, with $I^{131}$, doses of the order of 5,000 to 6,000 equivalent roentgens are necessary. (The equivalent roentgen is the amount of beta radiation which produces the same ionization per gram of air as 1 roentgen of roentgen rays.) If this is because some cells of the gland do not concentrate as much of the radioactive isotope as others, and these must achieve a certain minimum dosage, then other cells may have received as much as 20,000 to 30,000 equivalent roentgens. It is not known as yet whether the biologic effectiveness of a certain number of equivalent roentgens from an internal isotope irradiation is the same as that of the same number of roentgens from externally administered roentgen rays.

In conclusion, it appears that the possibility of late malignant degeneration is negligible following roentgen therapy for toxic goiter. It may be presumed that the hazard is not much greater for radioactive iodine therapy, but this cannot be verified for a number of years. Only a long term follow-up of an extensive series of cases will finally determine the safety or danger of this procedure. Accordingly, for some years at least, everyone employing this method should make all possible efforts to follow cases persistently. In the meantime the material should not be used indiscriminately. Reasonable criteria should be established for the selection of patients, and dosage levels should be based on careful calculations. In addition, careful histologic study of any thyroid material obtained at operation or autopsy at both short and long intervals after $I^{131}$ therapy should be undertaken.

## EFFECTS OF EMOTIONS ON GASTRO-INTESTINAL PHYSIOLOGY

*To the Editor:*—The writing of this letter is prompted by the editorial entitled "A Female Alexis St. Martin" which appeared in the June 11 issue of THE JOURNAL. There are errors of fact and errors of logic in this editorial.

The statement is made, ". . . in all men previously studied, beginning with Alexis St. Martin, resentment, anger and similar emotions were nearly always followed by hyperemia, hypermotility and hypersecretion of the gastric mucosa." Quite to the contrary, Beaumont records only inhibition of gastric motor and acid secretory activity accompanying emotional storms in Alexis St. Martin.

Actually, aside from the writings of Wolf and Wolff there are only a few incidental or poorly documented references to the occurrence of hyperactivity of the stomach at times of emotional stress. In contrast with the abundant evidence showing depression of gastric movements and secretion during affective states, the existence of the phenomenon of heightened activity as a concomitant of emotional upsets is poorly supported by evidence.

Finally, I wish to point out the logical fallacy involved in the notion that the recent findings of Crider and Walker indicate that a sex difference exists in regard to the effect of emotions on gastric function. When one says that a sex difference exists for any set of observations, this means that a correlation exists between the sex of the subjects and the presence or absence of some attribute. Now a correlation can be established only on the basis of the observation of a sizable number of subjects. To conclude, even as a conjecture, that a sex difference exists on the basis of the observation of one female subject is nonsense.

M. I. GROSSMAN, M.D., Chicago.

COMMENT.—Part of the purported error of fact referred to is probably due to unexpressed differences in various emotional states. True, depressive states have long been known to produce inhibition in the gastric activity. Emotions associated with internal conflict, such as resentment, unexpressed anger, anxiety, etc., tend, in the male stomach at least, to provoke the opposite reaction. True also, Wolf and Wolff were probably the first to clearly differentiate this difference in gastric response to emotion. It was the stimulatory effect of resentment, etc., to which the female patient reacted so differently.

In regard to the purported error of logic, conclusions were not drawn from this case, only a suggestion as to a possible relation. It would indeed be a sad state of affairs if conjectures and surmises were excluded from thinking. If this were so, many ideas and theories which eventually prove scientifically sound would never have reached the light of day.—ED.

# Medical Motion Pictures

## FILM REVIEWS

**Why Won't Tommy Eat?** 16 mm., color, sound, 594 feet (1 reel), showing time nineteen minutes. Produced in 1948 by Crawley Films for the Department of National Health and Welfare. Procurable on rental or purchase from the National Film Board of Canada, 620 Fifth Avenue, New York 20, and 400 West Madicon Street, Chicago 6.

This film portrays the relationship between the mother and child in diet problems. It illustrates the problem of a child who refused to eat properly and traces in detail the foundation of food habits to his early childhood. Finally it brings out that because of the mother's tense and impatient manner in handling the child she herself is the crux of the problem and must learn to understand her child's personal requirements both at meal times and with respect to his entire home life. This production can be recommended for showing to medical students, nurses and teachers where children eat in school, as well as social workers, parent-teachers' association, children guidance study groups and classes in family living at the senior high school and college level. Physicians will be interested in this film as a means of education of parents in relation to their important problem. The photography is very good.

**Invisible Armour.** 16 mm., black and white, sound, 706 feet (1 reel), showing time twenty minutes. Produced in 1948 by the National Film Board for the Department of National Health and Welfare, Ottawa. Procurable on rental or purchase from the National Film Board of Canada, 620 Fifth Avenue, New York 20, and 400 West Madison Street, Chicago 6.

This is a documentary film showing excellent technics of community organization. The procedures used in this diphtheria immunization campaign serve as a pattern for any similar health project. High school students act as publicists; churches and schools place the issue before parents, a committee makes a house to house survey and service clubs provide "toxoid taxis." Community awareness of a public health problem has been a motivating factor in stimulating community action to promote a successful immunization campaign. The settings, narration and situation definitely identify the film as being of Canadian origin, although a program of this kind could be applied to any section for any type of epidemic. From a health education standpoint, there should have been some mention of a child's routine visits to the family doctor. This motion picture should prove helpful and interesting to groups involved in community organization. Photography is good and narration is satisfactory.

# Bureau of Medical Economic Research

## MEDICAL ECONOMIC REVIEWS AND ABSTRACTS

Prepared by the Staff of the Bureau of Medical Economic Research

**The Development of Unemployment Insurance in the South.** By W. R. Curtis. South. Econ. J. 15: 43-53 (July) 1948.

This article attempts to evaluate the present social security measures with a view to determining the advisability of suggested changes.

A Wisconsin unemployment insurance law was passed in 1932; the Social Security Act was passed in 1935. In the South evidences of public interest prior to this time are lacking.

The Southern states were forced to accept enactment of state *laws by the provision that they could offset state tax against* the national tax up to 90 per cent of the federal levy by so doing. Although the Southern states are to be commended in this step, their coverage, amounts of benefits and conditions of eligibility have increased less rapidly than in other states. Coverage is one third in comparison with one half in the other states, largely because of the agricultural population, which is excluded from the act. Benefits are less now in amounts and durations. While other states have increased the maximum benefits from $15 a week, until half grant more than $20, only 31 per cent of the Southern workers are in states granting these benefits.

Although the maximum yearly benefits for 86 per cent of the workers as a whole are $350 or more, only 26 per cent of the Southern workers have acquired these benefits.

From the evidence of the widening gap between the provisions of the Southern states and those of the rest of the nation, the author concludes that Social Security has not been completely accepted by the public as elsewhere, making it probable that in the advent of the present proposal to change the 90 per cent offset against federal tax to 100 per cent, the gap would widen even more, until Southern industrialization lessened it. In addition, the author objects to this proposal on the ground that it would be difficult to retain national interest without federal financial participation.

Although the article serves to point out the limitations of the current proposal and the South's dual need for broader coverage and more liberal benefits, the side remark that over a ten year period, even in the Southern states, 2 per cent has been proved an adequate federal taxation is not supported by good evidence. The plan has not yet been tested in a time of depression.

**The Distribution of Physicians and Physicians' Services in Colorado, 1948. (Preliminary report.)** By. H. J. Dodge, M. M. Clapper and W. Darley. Rocky Mountain M. J. 45: 557-563 (July) 1948.

This report by the University of Colorado School of Medicine is a noteworthy contribution to knowledge on the distribution of physicians and medical service. The report presents an integrated picture of the total number of physicians, their status in practice and distribution by age, by size of community and by specialization. An effort is made to evaluate socioeconomic relationships between distribution of physicians and size of community, density of population and income status of the population. On a statewide basis, at least in Colorado, proportionately equal numbers of younger physicians have established practices in communities of various sizes, refuting the general statement that younger men are not establishing themselves in small towns. Perhaps this is a result of the University's long range program of emphasizing the training of general practitioners to meet the needs of its resident population.

Two charts and one table present the results of thinking through the problem of population-physician ratios. By the arbitrary county system of computing population-physician ratios, the range was between 380 and 6,200 persons per physician, with three counties listed as without available physicians. The researchers *did not think in terms* of arbitrary boundaries around each of the sixty-three counties, but delineated a total of fourteen medical service areas, including up to ten counties in each area. In fourteen medical service areas the ratios were found to range from a low of 450 persons per physician in the Denver metropolitan area to 1,890 in a relatively depleted area. One might question, however, whether the simple amalgamation of whole counties into larger geopolitical units is the most accurate means of establishing economic areas, for either medical service or any other type of consumer purchases. This following of county boundaries without exception seems contradictory to their statement that "it was necessary to recognize the fact that medical service does not stop at city, county or even state boundaries, so that one must consider medical service in terms of areas."

This report is only the first in a series on the problems of professional resources in the state. The study is being made with the cooperation of the School of Medicine, the Colorado State Medical Society, the Colorado State Board of Medical Examiners and the Colorado State Board of Basic Science Examiners.

**The Health Officer in Post-War Britain.** By Sir Allen Daley. Am. J. Pub. Health 38: 325-330 (March) 1948.

The reorganization of Britain's public health system represents a radical departure from schemes of the past. This new program consists of three main parts.

1. Hospital and Specialist Services: At present, hospital services are provided by local authorities, supplemented in most areas by voluntary hospitals. Plans are now drawn for a central government to take over all hospitals not run for private profit, on the theory that competition between municipal and voluntary institutions will disappear and that larger areas will reduce administrative and financial problems. The country will be divided into fourteen hospital regions, each governed by a regional board, nominated by the Minister of Health. This board will, in turn, delegate the functions of management to local committees, each responsible for one thousand beds. All specialists will have hospital attachments and will be under supervision of the regional boards.

Under this revised plan, medical officers will no longer control cases of tuberculous infection and tuberculosis hospitals. They will depend on the cooperation of the management committees.

2. General Practitioner Service: Previously, general practitioners operated under the jurisdiction of a local insurance committee, one of which existed for each local health department. Physicians and dentists have always fought control of the committees by medical officers, and in 1912 the representation of the local authority was reduced. Under the new program, it will again be increased to one third of the total number on the committees, although the medical profession will retain some strength in the councils.

3. Local Health Authorities: The local health authority will continue to control and develop environmental health services. These include child welfare, midwifery, visiting, home nursing, after-care, ambulance and immunization and vaccination services. In addition, health centers will be organized on a local basis under which general practitioners will engage in group practice. Doctors and dentists will be paid by executive councils, and conditions of service will be settled by negotiations between the Ministry of Health and the professions.

This drastic reorganization creates many new problems. The separation of health and hospital services necessitates liaison committees and conferences, taking up time that might otherwise be spent in executive or field work. After the plan is put into operation, many changes may be required before it can be regarded as more than an experiment.

**International Trends in Health Care.** By J. B. Grant. Am. J. Pub. Health 38: 381-397 (March) 1948.

The International Health Division of the Rockefeller Foundation has surveyed twelve leading countries (Australia, Canada, Denmark, England, Finland, France, The Netherlands, New Zealand, Norway, Sweden, Switzerland and the United States) in a study of the work and literature on health care. *The* foundation defines the aim of health care as "the full development and maintenance of man's mental and physical capacity," including in its scope nonmedical as well as medical factors. This principle is widely accepted today and is a part of the policy of most medical organizations, among them the American Medical Association.

*Nonmedical Factors.*—1. General Security: Social welfare legislation has generally preceded legislation based on strictly medical considerations. Today, New Zealand, Britain, France, and Sweden—as leaders in this field—provide cash allowances for families, free school meals and milk, maternity grants and home aid services. Under the British National Insurance Act of 1946, social insurance costs will require 10 per cent of the national income; in the United States, 1946 federal expenditure on social welfare amounted to 1 to 3 per cent of the national income.

2. Housing: The most "advanced" government housing policies are based on the social welfare concept of population needs. Sweden typifies this policy in its government subsidies to keep rents below 20 per cent of wages and in its system of family rent allowances.

3. Nutrition: All European countries, led by Great Britain and Sweden, are adopting food policies including free or subsidized protective foods to low income groups, free school lunches and price control backed by government subsidies.

4. Recreation: Britain is the leader in the field of mental, social and physical recreation, with an increasing number of community centers, mandatory under the Education Act of 1944.

5. Education: All twelve countries surveyed have either health "propaganda" or school health instruction. In the new workshop technic developing in the United States and Canada, community leaders discuss medical care materials under the direction of trained personnel.

The trend emerging from this nonmedical legislation is toward a welfare program based on a population policy designed to improve the quality of the people by removing the causes of social ills.

*Medical Factors.*—The Rockefeller Foundation lays down three prerequisites for the provision of medical service: removal of any economic barriers, adequate and geographic distribution of medical facilities and personnel and high technical excellence of the personnel and their tools.

1. Removal of Economic Barriers: The major defects in medical insurance plans found by the Rockefeller Foundation survey are: insufficient numbers of trained personnel to implement the plans, legislation for sickness rather than for health and inadequate provision for chronic, mental and rehabilitation services.

2. Geographic Distribution of Facilities and Personnel: The chief aspects considered here are regionalization of institutions, bed requirements and the number and functions of health centers.

Regional distribution of facilities has been recognized as a need in several of the countries surveyed. The over-all pattern now emerging consists of institutions at three or four levels, with health centers at the outskirts, community and district hospitals throughout the area and a teaching base hospital at the center. The base hospital provides refresher and training courses to physicians and technical personnel and holds pathologic conferences and teaching clinics. It lays down staff requirements for the smaller hospitals and provides specialists to supervise their personnel. This scheme, although not yet fully developed, should establish complete diagnostic service and continuation and graduate education.

Hospital bed requirements vary from community to community, but the estimate of the Hospital Council of Greater New York—16.1 beds per thousand population—agrees with the results of several other surveys conducted in both the United States and abroad. Recent studies have been made to determine the number of beds needed for mental, chronic and rehabilitation services. The United States is well in advance of other countries in establishing standards for hospitals.

Health centers are the determining factor in community health care. British estimates of the size of the urban population to be served by each center differ from 10,000 to 25,100 persons. The United States Survey and Construction Act provides one rural health center for a population of 30,000—a conservative estimate compared with that of other countries.

3. Medical Personnel—Numbers and Training: Technologic advances in the past century have brought into existence a number of auxiliary medical workers. These include nurses, medical and psychiatric social workers, dietitians, occupational and physical therapists, medical record librarians, medical and dental laboratory assistants, x-ray technicians and dental hygienists. The United States is still the only country requiring registration of such personnel.

Approximate figures as to the number of doctors and dentists required for a given population have been reached by empiric methods. A mean estimate may be found in the accompanying tables.

Standards for the training and registration of professional personnel have been worked out to the highest degree in the United States. The American Medical Association supplies a continuous revision of minimum essentials with respect to acceptable medical schools, internships, residencies and fellowships and approved examining boards. The American Dental Association sets corresponding standards for the dental profession. The American Council on Pharmaceutical Education has accredited certain colleges of pharmacy, and the National League of Nursing Education sets standards for nursing. The Committee on Professional Education of the American Public Health Association puts out a periodic revision of qualifications for public health personnel.

**Physician Requirements**

| | Population |
|---|---|
| 1 General practitioner | to 1,500 |
| 1 Surgeon | to 10,000 |
| 1 Eye, ear, nose and throat | to 15,000 |
| 1 Internist | to 30,000 |
| 1 Gynecologist and obstetrician | to 20,000 |
| 1 Pediatrician | to 30,000 |
| 1 Roentgenologist | to 60,000 |
| 1 Pathologist | to 100,000 |
| 1 Urologist | to 65,000 |
| 1 Orthopedist | to 100,000 |
| 1 Dermatologist | to 100,000 |
| 1 Psychiatrist | to 100,000 |

**Dental Requirements**

| | Number 100,000 Population |
|---|---|
| Dentists | 99 |
| X-Ray technicians | 27 |
| Hygienists | 45 |
| Laboratory technicians | 18 |

*The Pattern of Tomorrow.*—In the future, group practice by general practitioners will increase through the health centers, and physicians will be responsible for prescribing measures for the community against whatever forces interfere with "the full development and maintenance of man's mental and physical capacity." The medical profession must provide community health care, with the family, rather than the individual, the unit of practice. If physicians are to reorient themselves to their responsibility in providing such care, medical education must be extended to include social as well as clinical pathologic diagnosis.

In the United States, medical schools are now organizing to promote comprehensive health care on a prepayment basis for persons in the community and are making group clinics available for teaching purposes. In Britain, several medical centers are experimenting with the control of medical care facilities in their areas.

**A Report on the Results of Antivivisection.** By The National Society for Medical Research, 28 E. Washington St., Chicago 2.

A survey conducted by the National Society for Medical Research among 48 medical schools, 8 dental schools, 3 veterinary schools, 2 hospitals and 1 government health agency revealed that these institutions consider their work in protecting and improving public health hampered in both research and teaching by antivivisectional obstructions.

This occurs in two ways: (1) through restrictions on the kinds of animals usable; this limits the number obtainable; (2) through the hindering increase in costs which results from this false shortage of animals. Thus, less desirable animals are used, medical students are limited in their training and research workers in cancer, poliomyelitis, heart disease and tuberculosis are slowed in their battle against these afflictions.

As an ironic result of antivivisection propaganda and action, not only is new medical knowledge to help men, women and children retarded, but studies conducted for the benefit of pets and livestock are halted or hindered.

*(To Be Continued)*

## Medical Examinations and Licensure

### COMING EXAMINATIONS AND MEETINGS

#### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. Sept. 12-14. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

#### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc. *Oral.* Denver, Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

American Board of Dermatology and Syphilology, Inc.: *Written,* Various Centers, Sept. 15. *Oral.* Cincinnati, Sept. 15. Sec., Dr. George M. Lewis, 66 East 66th St., New York 21.

American Board of Internal Medicine: *Written.* Oct. 17. Asst. Sec.-Treas. Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 3. Final date for filing applications is Jan. 1. Sec., Dr. W. J. German, 789 Howard Ave., New Haven.

American Board of Obstetrics and Gynecology, Inc. *Part I.* Various Centers. Feb. 3. Final date for filing application is Nov. 5. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Ophthalmology: St. Louis, Oct. 15-19; Boston, December. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery. *Part II,* New York City, Feb. 9-10. Final date for filing application for Part II is Aug. 15. Address: Sec.-Treas., Dr. Harold A. Sofield, Room 1856, 122 S. Michigan Ave., Chicago.

American Board of Otolaryngology: Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Chicago, Oct. 7-8. Final date for filing application is Sept. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: *Oral.* Cleveland, Sept. 16-18; New York City, Oct. 21-23; Chicago, Dec. 9-11. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Preventive Medicine and Public Health: *Parts I and II.* New York, Oct. 22-24. Final date for filing application is July 22. Sec., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore.

American Board of Psychiatry and Neurology, Inc. *Special Examination,* Chicago, Oct. 24-25. December, New York City. Final date for filing applications is Sept. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Cincinnati, Sept. 28-Oct. 2. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, October 26. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: *Written,* December. *Oral and Clinical.* Chicago, Feb. 11-15. Final date for receipt of case histories is Sept. 1, 1949. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18.

#### BOARDS OF MEDICAL EXAMINERS

Alaska: * Juneau, Sept. 6. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

Arkansas: * *Examination.* Little Rock, Nov. 3-4. Sec., Dr. Joe Verser, Harrisburg.

District of Columbia: * *Examination.* Washington, Nov. 14-15. Sec., Dr. G. C. Ruhland, 4130 E. Municipal Bldg., Washington.

Georgia: *Examination.* Atlanta, Oct. 11-12. *Reciprocity.* Atlanta, Oct. 13. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O., San Francisco.

Illinois: Chicago, Oct. 4-6. Supt. of Registration, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June. Sec., Dr. Paul R. Tindall, 1138 K. of P. Bldg., Indianapolis.

Iowa: *Examination.* Des Moines, Dec. 5-7. *Reciprocity.* Des Moines, Sept. 5, Oct. 3, Nov. 7, Dec. 5. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 8-9. Sec., Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

Maryland: *Examination.* Baltimore, Dec. 13-16. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1. *Homeopathic. Examination.* Baltimore, Dec. 13-14. Sec., Dr. John A. Evans, 612 West 40th St., Baltimore.

Minnesota: * Oct. 18-19. Sec., Dr. Julian F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Montana: Helena, Oct. 3-5. Sec., Dr. Otto G. Klein, First National Bank Bldg., Helena.

Nevada: Carson City, Nov. 7. Sec., Dr. George H. Ross, 112 N. Curry St., Carson City.

New Hampshire: Concord, Sept. 8-9. Sec., Dr. J. S. Wheeler, 107 State House, Concord.

New Jersey: Oct. 18-21. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico: * Santa Fe, Oct. 10-11. Sec., Dr. Charles J. McGoey, Coronado Bldg., Santa Fe.

Ohio: *Examination.* Columbus, December. *Endorsement.* Aug. 2 and Oct. 2. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Pennsylvania: *Examination.* Philadelphia and Pittsburgh, July. Acting Sec., Mrs. B. G. Steiner, 351 Education Bldg., Harrisburg.

Puerto Rico: San Juan, Sept. 6-10. Sec., Dr. Luis Cueto Coll, Box 3717, Santurce.

South Carolina: *Examination.* Columbia, Nov. 8-9. *Reciprocity.* First Monday of every month. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

Tennessee: *Examination.* Memphis, Sept. 28-29. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Virginia: *Examination.* Richmond, Dec. 2-3. *Reciprocity.* Richmond, Dec. 1. Sec., Dr. K. D. Graves, 631 First St., S.W., Roanoke.

Wisconsin: * *Examination.* Madison, Jan. 10-12. Sec., Dr. C. A. Dawson, River Falls.

Wyoming: Cheyenne, Oct. 3. Sec., Dr. Franklin D. Yoder, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

#### BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau, Aug. 28. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, Sept. 20. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, Oct. 4. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

Colorado: *Examination.* Denver, Sept. 14-15. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 3.

District of Columbia: Washington, Oct. 24-25. Sec., Dr. G. C. Ruhland, 4130 E. Municipal Bldg., Washington.

Florida: *Examination.* Gainesville, Nov. 5. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

Michigan: *Examination.* Detroit and Ann Arbor, Oct. 14-15. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing 15.

Minnesota: *Examination.* Minneapolis, Oct. 4-5. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, Oct. 4-5. Director, Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln 9.

New Mexico: *Examination.* Santa Fe, Aug. 7. Sec., Miss Marguerite Kilkenny, 110 W. Houghton St., Santa Fe.

Oregon: Portland, Sept. 10 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

Rhode Island: *Examination.* Providence, Aug. 10. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Dakota: Vermillion, Dec. 2-3. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Wisconsin: Milwaukee, Sept. 24 and Dec 3. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

### American Journal of Diseases of Children, Chicago

**76**:485-608 (Nov.) 1948

BCG Inoculation and BCG Vaccination. A. Wallgren.—p. 485.
*Complications of Vaccination Against Smallpox. M. Greenberg.—p. 492.
*Electroencephalography of the Newborn: Studies on Normal, Full Term, Sleeping Infants. J. G. Hughes, Babette Ehemann and U. A. Brown. —p. 503.
Hemangioma (Capillary and Cavernous) with Thrombopenic Purpura: Report of Case with Observations at Autopsy. H. K. Silver, P. M. Aggeler and J. T. Crane.—p. 513.
Pediatric Teaching Facilities: Actualities and Hope. J. L. Wilson —p. 521.
Desirable Correlations Between Pediatrics and Preclinical Departments. A. A. Weech.—p. 528.
Desirable Correlations Between Pediatrics and Other Clinical Departments. R. McIntosh.—p. 533.
Makeup of Complete Pediatric Department. I. McQuarrie.—p. 541.
Undergraduate and Postgraduate Pediatric Education in Medical Schools. W. C. Davison.—p. 545.

**Complications of Vaccination Against Smallpox.**—According to Greenberg, approximately 5,000,000 persons were vaccinated in New York City during April and May 1947. A random sampling of 25,295 vaccinated persons indicated that 74 per cent had successful takes and were therefore susceptible to smallpox. There were observed 45 patients with postvaccinal encephalitis, a ratio of 1 to 110,000 vaccinations. There were 4 deaths. Of the patients who recovered, only 2 had residual pathologic signs; one, hemiparesis, and the other, optic neuritis. Forty-five patients had generalized vaccinia; 28 had a preexisting dermatosis, usually eczema. Of the 45 patients, 28 had not been vaccinated; all but 1 had been in intimate contact with someone recently vaccinated, and all but 1 were children under 5 years of age. Two infants died; neither had been vaccinated, but both had been in contact with a vaccinated person. Only 1 death occurred as a result of infection of a vaccination area. There occurred 9 per cent of false positive serologic reactions for syphilis in a group of 133 known nonsyphilitic subjects. A preliminary study of infants born to women who were vaccinated in the first four months of pregnancy indicated no increase in the ratio of congenital defects as compared with that for a control group.

**Electroencephalography of the Newborn.**—Hughes and his associates made 167 electroencephalographic tracings on 113 full term, apparently normal infants, ranging in age from 20 minutes to 6 days. A total of 72 infants on whom 82 electroencephalographic tracings were obtained constitutes the basis of this report. Thirty mothers were given caudal analgesia without indication of sensitivity reactions, a drop in blood pressure or any abnormal manifestation. Forty-two mothers were delivered spontaneously without administration of drugs, except for 8 who received a few breaths of ethylene and oxygen during the second stage of the delivery. The tracings obtained on the infants born of these 8 mothers did not differ from those of the infants whose mothers received no agent. The tracings obtained from babies born spontaneously without maternal sedation were practically identical with those obtained from infants born of mothers given caudal analgesia. The authors describe some of the differences observed. In all the electroencephalographic tracings obtained for both groups of infants the amplitude was low in comparison to the amplitude of tracings obtained beyond the neonatal period. The observations give objective evidence from the electrical standpoint of the functional cortical immaturity known to exist in the newborn.

**Anticoagulant Therapy for Cardiovascular Diseases.**—Foley and Wright maintained 7 men and 12 women between the ages of 25 and 66 years, with various thromboembolic conditions, for periods of five to twenty months (average eleven months) on dicumarol.® Their prothrombin time has been checked every seven to fourteen days after being carefully standardized at more frequent intervals during several weeks or months of hospitalization. The aim was to determine a daily dose of dicumarol® which would maintain the prothrombin time at 30 to 35 seconds, for which the term "therapeutic level" has been coined. The average weekly dose of dicumarol® required to maintain this level varied from 175 mg. to 800 mg. No thromboembolic episode occurred while the prothrombin time was at the therapeutic level. There have been no deaths in this series despite the seriousness of the condition of many of the patients at the time therapy was instituted. This method requires constant vigilance on the part of the physician and faithful cooperation from the patient. It necessitates a laboratory skilled in determining prothrombin time. Neither age nor weight constitutes the determining factor in the dosage requirements. An adequate protein intake helps to stabilize the requirements in some patients. Excessive alcoholic intake may affect the requirement. Prothrombin times of more than 300 seconds have occurred without serious hemorrhage. Sixty seconds is regarded as the upper limit of the desirable and safe therapeutic range. Excessive prothrombin times have all been controlled with vitamin K in adequate doses and whole fresh blood transfusions. This method of therapy has enabled most of these patients to lead fairly normal social lives and to support themselves and their families.

**Effects of Myanesin® on Central Nervous System.**—Gammon and Churchill administered myanesin® (3-ortho-toloxy-1,2-propanediol) by intravenous route to 35 patients with various pathologic states. Injection of a 1 or 2 per cent solution rapidly up to 1 Gm. established the action. The effect lasts for a few minutes to one hour. To maintain action after the initial dose it is necessary to infuse about 1 mg. per kilogram of body weight per minute. Parkinsonian tremor was abolished in 7 cases without impairment of strength or consciousness, an action which is unique. The tone of these patients was reduced. Choreoathetosis was reduced or abolished in 4 cases, confirming other observations. Senile tremor was improved but the tremor of multiple sclerosis was increased in 2 cases. One case of Huntington's and 1 of congenital chorea were unaffected. Brief discharges associated with anterior horn cell disease were not affected as in fasciculations of amyotrophic lateral sclerosis and organic facial hemispasms. The spasm of tetanus was abolished. A sensory effect was noted in the abolition of tabetic pain and an exaggerated second pain response, and in causalgic pain. Phantom limb pain was unaltered. These observations suggested a differential depression of function in the basal ganglions, brain stem and thalamus. The conclusion was strengthened by the abolition of petit mal discharges in 6 cases by a dose which did not affect the normal encephalogram or the discharge from a cortical scar. Improvement in certain psychoses was suggested by preliminary observations of the effect of the agent in 1 patient with reactive depression, in 1 deteriorated negativistic schizophrenic patient and in 1 agitated patient who would not respond to other medication. The transitory action of the drug limits its therapeutic possibilities.

**Penicillin in Pneumococcic Meningitis.**—Dowling and his co-workers treated 21 patients, 5 children between the ages of 3 days and 2 years, and 16 adults between the ages of 33 and 81 years, with pneumococcic meningitis, with 1,000,000 units of penicillin intramuscularly every two hours. Three of them received a single intrathecal injection of penicillin. Thirteen patients received sulfonamide compounds in addition. There were 8 deaths (38 per cent), compared with 41 deaths (62 per cent) among the 66 patients previously treated with smaller doses of penicillin by intramuscular route plus repeated intrathecal injections of penicillin. In patients who recovered the temperature dropped more rapidly among those who received massive systemic doses than among those who were given repeated intrathecal injections. Likewise the duration of pleocytosis was shorter in the former group. Since the results of massive systemic penicillin therapy in pneumococcic meningitis are at least as good as and apparently better than those obtained with the conventional systemic doses of penicillin plus multiple intrathecal doses, it is recommended that all patients with pneumococcic meningitis be given 1,000,000 units of penicillin intramuscularly at two hour intervals. Patients in coma when treatment is instituted may be given a single initial intrathecal dose of penicillin in addition. Sulfonamide compounds do not appear to be necessary when these doses are used.

**Treatment of Bilateral Retinoblastoma.**—The combined treatment for bilateral retinoblastoma employed by Reese and his associates consists of the surgical removal of the eye with the more advanced lesion and the application of fractional roentgen irradiation to the remaining eye in an attempt to conserve vision. Fifty-five patients have been treated by this method since 1933 and 53 of these are available for statistical analysis. Twenty-five are living with vision of 20/200 or better; 16 are alive but blind and 12 have died of retinoblastoma. Of the 19 patients followed up for five years or more 6 are living with vision of 20/200 or better; 6 are living without recurrence but blind and 7 have died of the disease. The roentgen ray treatments are applied three times a week to alternate temporal and nasal portals in doses of 400 r per portal during each treatment. Treatments are continued for three and one-half months, until a total of 8,000 r has been applied to each field.

**Effects of Sympathectomy in Hypertension.**—According to Wilkins and his associates little is known concerning the vascular or metabolic effects of sympathectomy in hypertension. Patients with essential hypertension selected for splanchnicectomy have been made available for study by the authors through the cooperation of Dr. Smithwick, under whose direction sympathectomy was performed. They were studied before and again, if possible, within three weeks after bilateral operation, usually of the lumbodorsal type. In addition, some patients were studied a third time four to ten months after operation, whereas a few patients were studied only once—from one to nine years postoperatively. Studies on the hemodynamic effects of sympathectomy revealed (1) little change in basal cardiac output, (2) an early increase and later moderation in hepatic-portal blood flow, (3) a decrease in the splanchnic vasoconstrictor response to the upright position and (4) a decrease or abolition of vasopressor overshoots of arterial pressure after depressor procedures. The postoperative effects are similar whether or not arterial pressure is lowered, except that hepatic-portal blood flow apparently is influenced directly by the level of the arterial pressure. These results, along with the reported studies on renal blood flow, indicate that the direct hemodynamic effects of splanchnicectomy do not account for any lowering of arterial pressure that may occur. It is possible that in some patients indirect physical or chemical mechanisms resulting from these hemodynamic effects may in time act to cause a widespread decrease in peripheral resistance and a lowering of arterial pressure.

**High Dorsolumbar Sympathectomy for Hypertension.**—Evans and Bartels of the Lahey Clinic evaluate the results of operation based on a six month to three year follow-up on 173 patients who underwent a high dorsolumbar sympathectomy from the fourth thoracic to the second or third lumbar ganglion. This study was undertaken to ascertain whether a larger number of patients were being aided than by lower sympathetic resection. Although the present series has been followed a shorter time, and doubtless with the passage of one or two more years the difference in figures will not be so marked, the superiority of results in patients with group III fundi (hemorrhage and exudate) has doubled, from 21 to 44 per cent. Poor results have dropped one third, from 37 to 13 per cent. Good results in patients with groups I and II fundi have almost doubled, from 39 to 74 per cent, and poor results are less than one half, having dropped from 23 to 9 per cent. The principal effect of splanchnicectomy on hypertension is orthostatic; symptomatic relief is parallel to drop in orthostatic rather than supine blood pressure. High dorsolumbar sympathectomy did not protect 8 patients among the 173 from subsequent cerebrovascular accident, fatal in 2 cases. Angina was wholly or partially relieved in 9 of 15 patients. Ninety per cent of patients with abnormally wide transverse diameters of the heart showed reduction of heart size, 64 per cent to normal. There was improvement in 21 of 50 patients who had abnormal electrocardiograms. Thirty-four of 45 patients with nocturia reported complete or partial relief. At least one renal function test showed improvement in 33 of 55 patients who had one or more tests indicating impairment before operation. Retinal vascular change improved in two thirds of 117 patients. Operative mortality was 0.5 per cent; mortality rate within the follow-up period of six to thirty-three months was 7 per cent. The authors do not consider this type of operation with its prolonged convalescence as a prophylactic operation for benign hypertension but urge it on patients under 50 years of age with spastic, exudative and hemorrhagic retinal arteriolar changes, moderate cardiac damage, signs of early nephrosclerosis and labile blood pressure.

**Carinamide and Blood Concentration of Penicillin.**—Zeller and his associates administered carinamide orally to 106 patients in an effort to determine its ability to increase the concentrations of penicillin in the serum. The average increase in serum penicillin concentrations attained with the use of penicillin plus carinamide over that obtained with the use of penicillin alone was approximately fourfold, regardless of the route of administration of penicillin. The acute toxicity of carinamide is negligible. The chronic toxicity is as yet undetermined. A recommended dose of carinamide is 4 Gm. every four hours. Carinamide is used to best advantage clinically in combination with penicillin administered orally.

**Changes in Brain After Electronarcosis.**—According to Alpers and Madow the prolonged application of electric current to the brain to produce a narcosis-like state has been used as a psychiatric treatment since 1944. When the current is first applied at the initial dose of 160 milliamperes, there is usually an immediate tonic flexion of the extremities, followed, after ten to fifteen seconds, by extension. There is an initial short cardiac arrest, after which the heart beats slowly and often irregularly. The face and often the neck and chest become flushed. After thirty seconds the high initial current is lowered to from 60 to 70 milliamperes. The tonic contraction relaxes and is replaced by weak clonic twitches. These movements are usually over in ten seconds. With slight adjustment of dose, the state of electronarcosis, in which the patient is quiet but has developed considerable flexor tone in the arms and extensor tone in the legs, is maintained for seven minutes. In schizophrenia this treatment has been found to compare favorably with insulin shock and has been found superior to standard electric shock. Although deaths have resulted in dogs, no serious complications have been recorded as a result of this treatment in human subjects. The authors, however, present the case of a woman, aged 28, who died three hours after her first treatment with electronarcosis. The pathologic changes found in her brain were distinct, recent hemorrhages in the caudate nuclei, the medial nucleus of the thalamus, the posterior hypothalamic nuclei, the supraoptic nucleus, the cerebellum and the choroid plexus of the lateral ventricles. There were fresh, smaller hemorrhages in the cerebral cortex, the corpus callosum, the optic tract and the pineal gland. These changes must be considered related to the treatment, in view of the time relation, the nature of the lesions and the absence of any other probable causative agent.

**Encephalography of Multiple Sclerosis.**—According to Zeifert, at the University of Michigan Hospital diagnosis of multiple sclerosis was made in 485 cases in the five year period ending March 31, 1947. Electroencephalographic studies were made in 44, but 10 of these are excluded because their case histories failed to meet the strict diagnostic requirements that were set up. The electroencephalograms in the remaining 34 cases were analyzed, and in all of them the disease was in exacerbation at the time of the electrical recording. Most of the records were made with the Grass three channel, ink-writing oscillograph. A few were made with the six channel Grass apparatus. Ordinarily, ten electrode placements were made, but in cases in which focal signs appeared or the clinical record pointed to focal activity, additional electrodes were used, the total number varying from seventeen to twenty-six. Fifteen of the 34 patients had profoundly abnormal electroencephalograms, and in 11 of these 15 focal signs were present. Mildly abnormal records were present in 6 of the patients and borderline records in an additional 8 cases. Only 5 of the 34 patients had entirely normal electroencephalograms. Surprisingly little correlation was found between the colloidal gold curve and the electroencephalogram. Although 62 per cent of the patients had abnormal electroencephalograms, only 14.7 per cent had first zone colloidal gold curves. Although this series revealed no electroencephalographic signs specifically diagnostic of multiple sclerosis, the author feels that in obscure cases with no objective evidence of cortical or subcortical involvement the electroencephalogram may be used to differentiate multiple sclerosis from pure spinal cord disease.

**Lymphosarcoma of Eyelid with Rapid Fatal Termination.**—Stansbury reports the case of a man, aged 49, who on May 9, 1947 consulted his physician with the complaint that a hot chip of metal had flown into his right eye two days previously. The piece of steel had been removed immediately, but the following day the eye was red, with a purulent discharge. His physician made a diagnosis of acute purulent conjunctivitis and prescribed sulfathiazole ophthalmic ointment. On May 14 there developed an inflammation of the right lower lid which subsided with treatment. Two weeks later the lids of the right eye began to swell. On June 2 hospitalization for the administration of penicillin was advised. After two days of this regimen sulfadiazine was combined with the penicillin, and on June 9 they were both discontinued and treatment with streptomycin was instituted. Two days later penicillin was given again, this time in combination with streptomycin. An ophthalmologist made a diagnosis of orbital cellulitis and abscess of the lid. Incision into the apparent abscess yielded no discharge. On June 18 the antibiotics were discontinued. On June 24 the patient presented a hard, red swelling of the right eyelid and the right side of the face. The impression was that of a fungous infection of the right orbit and the right side of the face, but cultures revealed only a few nonpathogenic bacteria. A few small nodes became palpable in the right axilla. On June 30 a biopsy was performed on the mass over the angle of the jaw; microscopic examination of the sections disclosed a highly malignant lymphosarcoma of the reticulum cell type. The patient died on July 8. The case was unusual in that the lesion was considered an atypical, low grade inflammatory process, and the disease progressed rapidly to a fatal termination. Pathologically, the neoplasm is unique because of meager amount of involvement of the lymph nodes and the rapid, destructive spread to involve all the viscera and other tissues of the body.

**Cold Room in Treatment of Burns.**—Brown and De Lalla report a man with 50 per cent of his surface area burned. To maintain pressure over the burns, it was necessary to apply bandages over approximately 85 per cent of his surface area, the effectiveness of which was seriously diminished in its ability to lose heat. The extreme elevation of the body temperature (105 F.) of the patient was easily and quickly lowered to a normal range and then maintained at levels below 101 F. by placing the patient in a cold room adjacent to the hospital ward for three and one half days. A 1½ horse power compressor situated in an adjacent room was used as the cooling unit; temperatures as low as 40 F. and as high as 110 F. may be achieved, and any desired humidity obtained. Thereafter the patient's problem was one of long and difficult fluid balance and plastic surgery; he was eventually discharged with completely healed skin. A cool environment (65 to 70 F.) is of importance in the therapy of burns and burn shock, whether hyperpyrexia is present or not. If extremely high body temperatures are a factor, as in the authors' case, a cool environment becomes a critical necessity, the exact room temperature depending on the individual requirements. Two other cases of severe resistant hyperpyrexia, one that of a man aged 30 with pneumococcic meningitis and the second that of a girl aged 6 with bulbar poliomyelitis, showed that human body temperatures can be easily and quickly reduced from 106 F. to 98 F. and maintained near the normal level by the use of a cold room. The value of a chamber permitting control of the environmental temperature in tropical and subtropical zones is obvious. The usefulness of such a room to both military and civilian hospital facilities is emphasized.

**Effects of Folic Acid Antagonists on Leukemia.**—Farber reviews the present status of the use of folic acid antagonists in acute leukemia in children. Temporary remissions in acute leukemia, as marked as those caused by aminopterin,® have been produced by the use of two compounds closely related chemically to aminopterin® (4-aminopteroylglutamic acid)—a-methopterin® (4-amino-10-N-methylpteroylglutamic acid) and amino-an-fol® (4-aminopteroylaspartic acid), both of which are also toxic compounds. Despite the increasing number of patients in whom temporary remissions have been produced, with survival in some far beyond the usual course of the disease, no evidence has been presented which would justify the use of the word "cure" of acute leukemia. Further research for less toxic related compounds with even greater effectiveness is imperative. Two of the most pressing problems demanding solution are concerned with the nature, the prevention and the treatment of toxic changes, including hemorrhage, produced by these folic acid antagonists and the causes, prevention and mechanism of hemorrhage in acute leukemia. The use of the folic acid antagonists in the treatment of incurable cancer including leukemia must remain in the realm of research until answers are found to these questions.

**Use of Folic Acid Antagonists in Leukemia.**—Dameshek says that whereas Farber's observations were made chiefly on children, his were made chiefly on adults, only 4 of his 35 patients being children. The folic acid antagonists were dissolved in sterile isotonic sodium chloride solution, were injected intramuscularly daily until a toxic or pronounced hematologic reaction occurred, following which the drug was discontinued. The drug was then resumed in a maintenance dose when the toxic reaction had subsided. Aminopterin® was given in a dosage of 1 to 4 mg. daily, a-methopterin,® 2 to 5 mg. daily; amino-an-fol® 25 to 75 mg. daily, and a-ninopterin® (4-amino-9-methylpteroylglutamic acid) 5 to 15 mg. daily. Maintenance therapy was given either daily or every other day and either by intramuscular or oral route. Of the 35 patients, 1 has been under treatment for less than four weeks, and 8 died within one to five days after therapy was instituted. Of the remaining 26 patients, 9 have had continued or intermittent remissions for at least two months and up to eight and one-half months. Thus the folic acid antagonists seem to have the capacity to induce remissions in about one third of the cases of acute and subacute leukemia. Remissions are obtained most commonly in the lymphoblastic types, least often in the monocytic types. It is possible that folic acid is required by the primitive white cell as a growth factor. The folic acid antagonists may result in cell death by modifying various enzyme systems within the primitive cells. The proliferative process is by no means cured with aminopterin® treatment. Acute leukemia may be likened to "wildfire" which, although damped by aminopterin,® continues to smolder. There comes a point in the leukemic process at which both the leukemia and increasing toxicity to the drug make further progress impossible, and the patient dies. Other growth factors or enzymes are probably of importance in the metabolism of the primitive white cells, and when these are discovered and their antagonists synthesized, the therapeutic results in acute leukemia may be of more consistent and durable nature.

**Long-Continued Estrogen Treatment in Rabbits.**—Bern subjected a series of male Dutch rabbits, intact and castrate, to continuous treatment with estradiol and estradiol dipropionate for 159 to 633 days. The seminal vesicles were tremendously enlarged, and the epithelium of the prostate, vesicular gland and seminal vesicle underwent metaplasia to a nonsquamous, transitionoid type, adenomatous in appearance. No abdominal fibroids or prostatic fibromyoepitheliomas, as reported in the guinea pig, were found, but tumorous changes (fibromas and invasive epithelial proliferations) hitherto undescribed in male mammals after estrogenization were noted in the vasa deferentia and in the epididymides of certain rabbits.

**Effect of Diethylstilbestrol on Leukemia in Mice.**—According to Murphy and Sturm the Rockefeller Institute leukemia strain of mice shows a consistently higher incidence of the disease in females than in males. The rate in normal males during the period of the present study was 41.5 per cent and the females 70. Prolonged treatment of male mice with diethylstilbestrol increased the rate to 71 per cent, a close approximation to that shown by the control females. It is suggested that this result is due to the interference with the male sex hormone rather than to a direct action of the estrogen.

**Lead Poisoning from Embedded Bullet.**—McNally presents the case of a woman, aged 66, who on admission to hospital complained of epigastric pain and vomiting for the past nine days. She also complained of pain in the right knee from old arthritis. The hematologic report gave a suspicion of lead poisoning and led to further questioning of the patient. She stated that twenty-seven years prior to this examination she was accidentally shot in the right knee. Mental confusion, nervous excitability and dulness developed. The patient complained of headaches, exhaustion and pain in the abdomen, and gradually was unable to speak. She died on her forty-seventh day in the hospital. Necropsy revealed the presence of lead in the kidney, the sternum and ribs in amounts usually found in people who work in lead industry. The amount of lead found in the liver and heart was three times that found in persons dying with symptoms of lead intoxication and with a history of an exposure to lead. Similar instances of lead intoxication are cited from the literature, in which absorption of lead, and the onset of symptoms, were very slow. Thus it appears that bullets and shrapnel remaining in the body may become a source of plumbism, derange renal function and possibly retard wound healing.

**Acute Necrotizing Hemorrhagic Encephalopathy.**—Adams and his co-workers report 4 cases of acute necrotizing hemorrhagic encephalopathy in 3 men aged 46, 34 and 33, respectively, and in 1 woman aged 56. There were antecedent respiratory or gastrointestinal symptoms associated with fever in each case. After an interval of several days, during which the patient seemed about to recover, an acute exacerbation of the illness with a marked rise in temperature occurred. Severe headache developed and the neck was stiff. The patient became drowsy, confused and comatose. This was followed by hemiplegia, quadriplegia and convulsions. The cerebrospinal fluid was abnormal; neutrophil pleocytosis, elevated protein and normal or slightly reduced sugar were observed. There was a rapid decline and death occurred in one to two days after the onset of the acute illness. Necropsy revealed a large, asymmetric, discolored lesion extending widely through the brain stem or the semioval center. This lesion exhibited swelling and pinkish discoloration with multiple hemorrhages and involved pons, midbrain, subthalamus and cerebellar peduncles in 2 cases, cerebral white matter, internal capsule, cerebral peduncle on one side and the great commissure in the third case, and the white matter of one cerebral hemisphere and brain stem in the fourth case. The microscopic pathologic changes consisted of a widespread necrosis of one large discrete or several smaller confluent areas, partial vascular necrosis with fibrin impregnation of the vessel wall and fibrin exudation, multiple small hemorrhages and heavy neutrophil infiltration of the damaged tissues. No bacteria could be demonstrated by bacterial stains in any of the cases. All 4 cases occurred in the summer and autumn of 1946 at a time when there was no epidemic of virus disease of the nervous system. A distinctive neuropathologic reaction type is suggested similar to that which has been described in some of the reports of hemorrhagic encephalitis or leukoencephalitis. The cause and pathogenesis could not be ascertained. The possibility of an allergic reaction to a toxin or infective agent seems most consistent with the pathologic findings.

**Improved Diaper.**—McKhann and Bricmont mention disorders traceable to wet or soiled diapers and show that diapering involves hygienic and sanitary problems. Attempts have been made to improve the diaper so that it will be hygienically adequate, sanitarily effective and acceptable as a garment. They describe a diaper designed to collect urine and stool of the infant with minimum contamination of the baby's body and of his bed and clothing. The diaper consists of an envelope constructed to hold a pad. When properly inserted, the pad fits smoothly into the waterproof material covering both ends of the pad, keeping them out of contact with the baby, leaving only a small section in the middle of the pad directly exposed to the excretions. The arc action of the pad holds this section of the pad away from the baby. The insert can be removed by grasping the ends of the diaper garment and applying pressure in the middle with the thumbs. The pad will fall out. Illustrations depict construction, fit and mechanism of the diaper, which in clinical trials has proved 95 per cent effective for the purposes for which it was designed. It reduces the incidence of intertrigo and diaper rash and is not uncomfortable or unsightly. Whether it will materially reduce simple pyuria can be proved only by more extensive trials.

**Fatal Homologous Serum Hepatitis in Infant.**—Schmidt and Lee report the case of an infant who had severe diarrhea and vomiting when 3 weeks old. In the course of four days he was given two transfusions of whole blood of 50 cc. each and three 75 cc. pooled plasma infusions. The child improved rapidly and was discharged from the hospital several days later. A month later the child commenced to cry frequently without apparent cause. Examination at this time disclosed nothing of significance. At the end of the following month, the child had mild diarrhea and fever but improved and was discharged. He was returned on the following day. The terminal stage was sudden in onset with jaundice, multiple hemorrhages, and manifestations referable to the central nervous system. Necropsy was done four hours after death. In addition to the rarity of this disease in infants, two other factors add to the interest of this case. The first is the mild prodromal stage of the illness, a minor gastrointestinal disturbance with recovery, which gave no indication of the destruction of the liver which must have been present when the infant was discharged from the hospital. The second is the sudden onset of jaundice and prostration as the icteric and terminal phases of the illness. In the 3 other reported cases of this disorder, the infants appeared to be doing rather well until shortly before death, which occurred suddenly and unexpectedly. In adults the beginning of the terminal phase is usually abrupt, but the transition most frequently occurs more than one week prior to death.

**Streptomycin as Adjunct in Surgery of Pulmonary Tuberculosis.**—Mulvihill and co-workers used penicillin as an adjunct in the surgical treatment of 65 patients with tuberculosis of the lungs, pleura and chest wall at Triboro Hospital during 1947. Intrapleural procedures were performed in 19 of the 65 patients, comprising ten lobectomies, three total pneumonectomies, three pleural decortications and three intrapleural pneumolyses. In the 13 cases of resection, 0.5 Gm. of streptomycin was given intramuscularly every twelve hours for three to four weeks preoperatively and for ninety days postoperatively. In the remaining 6 cases 1 Gm. of the drug was given for seven days preoperatively and for fourteen days postoperatively. The patients came to operation practically dry as far as sputum output was concerned. The postoperative courses were benign. Neither contralateral nor ipsilateral spreads occurred in the immediate postoperative period, and late spreads or exacerbations have not been noted up to date. In a group of twenty-one lobectomies performed at Triboro Hospital in the prestreptomycin period of 1942 to 1946, 3 patients died eight to nine months postoperatively after development of bronchopleural fistulas, empyema and contralateral spread. The efficacy of preoperative and postoperative treatment with streptomycin in the prevention of postoperative complications was evident likewise in 23 of the 65 patients who were considered as substandard risks for thoracoplasty; there was a definite decrease in sputum output and postoperative courses were benign and uncomplicated. Twenty additional thoracoplasty patients who were not treated with streptomycin are included as controls. Beneficial effects are cited in 16 cases of topical application of the drug in combination with open operations for bronchopleural fistulas and residual tuberculous empyema spaces.

**Streptomycin in Surgery of Pulmonary Tuberculosis.**—Chapman and co-workers present a preliminary report on 800 patients treated with streptomycin at Herman Keifer Hospital and the Maybury Sanatorium. The patients at the Maybury Sanatorium received 1 Gm. of streptomycin once each day for six weeks for pulmonary tuberculosis only, either with or without collapse therapy or other measures, and the patients at Keifer in whom major surgical procedures have been contemplated or have been completed were given 0.5 Gm. of the drug once each day for twelve weeks. In group 1 were patients with early, minimal and moderately advanced disease in whom it was hoped that collapse or other surgical measures could be avoided or reduced in amount; streptomycin has decreased the necessity of collapse measures by over 50 per cent. Group 2 comprised patients in whom surgical procedures could be made possible through streptomycin. The number of patients in whom thoracoplasty was made possible was doubled by the administration of the drug. Group 3 comprised patients who received the drug as a prophylactic measure against spread following surgical and collapse procedures, or to clear these spreads if they occurred and to make the operation possible earlier. In this group many months of hospitalization were saved. Group 4 comprised patients with proved or suspected tracheobronchial disease. Results in proved ulceration were highly satisfactory; healing often occurred soon after the drug was started. Silver nitrate application was no longer necessary. The number of bronchoscopies performed for these lesions has been strikingly reduced. Results of treatment with streptomycin were most striking in soft, mixed and most recent lesions, but occasionally excellent results have been obtained in apparently old, fibrotic lesions. In almost all patients, some clearing of the lesions and clinical improvement have been noted. The authors arrive at the conclusion that streptomycin is not a substitute for but is an adjunct to bed rest and proper collapse measures.

**Streptomycin in Pulmonary Resection.**—Moore and his co-workers did seventy-four resections on 74 patients for pulmonary tuberculosis at the Veterans Administration Hospital at Oteen, N. C., and at the Western North Carolina Sanatorium at Black Mountains, N. C., from January 1947 to May 1948, with the use of streptomycin as a prophylactic agent. Of these thirty-five were lobectomies and thirty-nine pneumonectomies. One of the lobectomy patients died from hemorrhage shortly after operation, a mortality rate of 2.9 per cent. Of the pneumonectomy patients 5 died, an operative mortality of 13 per cent. The mortality rate of the total resections was 8.1 per cent. There have been no late deaths to date. Empyemas developed in 4 patients and were considered to be the result of fistulas. These were assumed to be tuberculous, even though the organism could not be demonstrated in all instances. Bronchial fistulas developed in 4 patients, probably from failure to maintain a tight closure of the bronchus. Spreads followed in 3 patients operated on. There have been no deep tuberculous wound infections and only a few minor wound infections following resection and no late spreads or empyemas to date, but there was progression of the disease in 1 patient sixteen months after operation. As compared with a series of 11 patients on whom resections were done by the authors prior to use of streptomycin, the mortality rate has been reduced from 36 per cent to 8.1 per cent; the rate of spreads from 27 per cent to 4 per cent; the rate of fistulas and empyemas from 55 per cent to 5 per cent, and the rate of sputum conversions has risen from 58 per cent to 87 per cent. Sixty-two of the 68 living patients (92 per cent) have a negative sputum. The authors feel that streptomycin has been the major factor in lowering the mortality and morbidity rate.

**Retropubic Prostatectomy.**—Moore performed retropubic, extravesical prostatectomy, following fairly closely Millin's technic, on 46 patients between the ages of 50 and 86. The results obtained were compared with those in two similar consecutive series of cases, in which patients had been subjected to primary suprapubic prostatectomy or to transurethral prostatic resection. All the patients were of a similar age group and were suffering from essentially the same degree of prostatic obstruction and were patients with much the same infirmities. Their examinations and preliminary preparation were along the same lines, as was also their postoperative care. There is definite evidence that retropubic prostatectomy is an operation perhaps more easily mastered than transurethral resection but somewhat more difficult than removal of the prostate by the suprapubic approach. The advantages of the retropubic approach from the standpoint of the patient appear definite in that the operation is concluded at one sitting, there is less bleeding postoperatively, the period of convalescence is about equal, the risk is no greater, there is less discomfort in the immediate postoperative period, the functional results in the main are superior and the period of hospitalization is shorter than in those dealt with suprapubically and about equal to those treated transurethrally. Osteitis pubis proved to be the most serious deterrent to the retropubic approach, occurring in 8 (17 per cent) of the author's patients from two weeks to five months postoperatively. Treatment consisted of rest in bed, the application of infra-red heat, intensive courses of streptomycin and penicillin and daily injections of thiamine hydrochloride. Should the prevention of this complication prove to be possible, retropubic prostatectomy perhaps will replace to a great extent suprapubic prostatectomy for hypertrophies of unusually large degree.

**Retropubic Prostatectomy.**—Bacon performed a retropubic prostatectomy on 102 patients between the ages of 51 and 96. In 75 patients the initial emergency was complete retention of urine and in 89 the urine was moderately or severely infected. Six specimens were malignant. The largest prostate weighed 190 Gm. and the smallest weighed 6 Gm. Six patients died, 2 on the day of operation, 1 on the second, 1 on the fourth, 1 on the fifth and 1 on the thirty-third postoperative day. Postoperative hospitalization averaged 17.1 days owing to the fact that the majority of the patients were poor surgical risks. In 1 of the patients osteitis pubis developed. As a preliminary consideration, and before actual application of the operation, investigation of the space of Retzius on the cadaver is suggested. In order to avoid misapplication of this technic to prevailing lesions, it is urged that an inventory of results be frequently considered. The retropubic approach has advantage of affording increased comfort during convalescence, prompt urinary control and preservation of sexual potency. The most useful purpose of retropubic prostatectomy is for the complete excision of large or medium hyperplasias.

**Osteitis Pubis.**—Lavalle and Hamm report 7 cases of osteitis pubis in men between the ages of 57 and 72 on whom a suprapubic prostatectomy was done from three to seven weeks before the onset of symptoms. These cases were definitely not infections of the space of Retzius. Early diagnosis was made on the basis of clinical signs alone. It may take one to nine weeks after the onset of symptoms to obtain roentgen confirmation, and treatment should not be postponed until this evidence is obtained. A vitamin B complex preparation was administered intramuscularly twice a day combined with daily short wave diathermy to the affected parts. Improvement occurred within three to six days. This treatment should be instituted as soon as clinical symptoms appear, and weekly roentgenograms of the pelvic girdle should be obtained for confirmation of the diagnosis. When this new therapeutic regimen to hasten recovery fails, recourse to high voltage roentgen therapy should be tried.

*Pheochromocytoma of Adrenal with Successful Removal: Report of Case. A. L. Forsgren, W. D. Nesset and D. M. Anderson.—p. 170.

**Prefrontal Lobotomy for Relief of Pain.**—Love and associates of the Mayo Clinic report 9 patients who suffered from intractable and uncontrollable pain in various parts of their body, and who were subjected to bilateral prefrontal lobotomy. In 4 cases the pain was on an organic basis; in the remaining 5 cases no organic cause could be found for the pain. In 6 cases the relief of pain was remarkable and was considered satisfactory. The results in 1 patient with severe diabetes who succumbed to his illness cannot be adequately evaluated. One patient was completely relieved for a time, but he subsequently presented a behavior problem. The other patient was under observation in a mental hospital at this writing; the headache for which the operation had been performed was less troublesome, but he presented a problem in management. The authors are of the opinion that the operation of prefrontal lobotomy is justified and indicated in certain carefully selected patients who have intractable pain, whether of organic or functional type, when less radical measures fail to give relief.

**Successful Removal of Pheochromocytoma of Adrenal.**—Forsgren and associates present the case of a man, aged 27, who had had paroxysmal hypertension for four years. Diagnosis of pheochromocytoma was made with the aid of the histamine test and roentgen visualization of the tumor by perirenal air insufflation. Successful operative removal has apparently resulted in a complete cure.

Acute Abdominal Conditions in Infancy. W. H. Breeden.—p. 27.

**Gastrointestinal Symptoms in Coronary Heart Disease.**—Yeagley and his associates point out that the gastrointestinal tract and the heart are so intimately associated through the vagus nerve that reciprocal disturbances are not surprising. The abdominal and gastrointestinal symptoms which frequently result from heart disease may be brought about by: (1) pain originating from the heart muscle itself but referred to the abdomen; (2) pain arising from congestion of the liver, spleen or other abdominal viscera secondary to congestive failure, and (3) pain arising from the localization of emboli thrown off from the heart. Abdominal pain, nausea, vomiting and liver enlargement are symptoms and signs which must be carefully evaluated in the differential diagnosis of cardiac and gastrointestinal disease. The authors made an analysis of 100 patients with proved recent myocardial infarction to determine the frequency and importance of gastrointestinal symptoms as manifestations of heart disease. They found that 40 of the 100 patients with proved myocardial infarct had abdominal pain and disorders of digestion. These symptoms rarely obscured the diagnostic features of the primary cardiac disturbance. In most instances, the presence of abdominal pain, tenderness, nausea and vomiting suggested a concomitant organic gastrointestinal disease. Physical and roentgen examinations carried out on these patients and the postmortem studies on 15 of them revealed that the majority of the patients had no associated organic gastrointestinal disease. This suggests that the abdominal complaints are often initiated reflexly from the heart itself, and are probably due to the proximity of the respective nerve pathways and related vagal reflexes rather than to congestion of the liver, spleen or intestinal mucosa.

**Bifrontal Lobotomy for Organic Pain.**—LeFever reports several cases in which lobotomy was carried out for the relief of organic pain. He had the opportunity to compare the relative merits of chordotomy and lobotomy in patients with similar lesions. He found that even though pain is relieved by chordotomy, there is still the fear of pain, whereas in the case of lobotomy both the pain and the fear of pain is eliminated. In the last 4 cases there was a structural basis for the pain. After lobotomy not only does the patient become indifferent to the pain, but he becomes oblivious to the fact that he harbors a serious illness. In the surgical procedures designed to relieve pain three stages can be differentiated. The first stage is the interruption of the peripheral nerve fibers (i. e., alcohol section or sympathectomy). In the second stage the central conduction pathways are cut in the cord, medulla or mesencephalon. In the third stage the anterior thalamic radiation is severed, producing a decrement in the psychic reaction to a painful stimulation.

**Sensitization to Penicillin.**—Feldman groups the adverse symptoms produced by penicillin into the following categories: It may act as a direct toxin or primary irritant; it may act as an antigen and stimulate antibody formation; it may induce a Herxheimer reaction; it may induce "therapeutic paradox;" it may induce organism resistance. The allergic reactions to penicillin, produced because of its antigenic properties, can be divided into several types: (1) allergic dermatitis of the contact type; (2) drug and serum-like reactions; (3) erythematovesicular group of reactions; (4) tuberculin type of reaction; (5) Arthus-like reactions. The allergic responses to penicillin may be severe and temporarily disabling. Spontaneous desensitization may occur. A plea should be made against indiscriminate use of penicillin. It is a highly sensitizing agent, and when it is used in minor disturbances, not only may these reactions result, but the patient may also become sensitized to future therapy with this valuable antibiotic agent.

**Electric Shock Therapy During Pregnancy.**—Doan and Huston add 7 new cases to the 9 previously reported, in which electric shock treatment has been used during pregnancy. The 7 patients reported here all received curare to soften the convulsions. One was treated in the first trimester, 4 in the second and 2 in the third. In all cases the pregnancy was not complicated by the treatment, and uneventful delivery of normal infants was accomplished at term. On the basis of this experience, and the reports in the literature, it would seem that pregnancy per se is not a contraindication to electric shock therapy. It also appears that curare may be used with safety.

**Hypopituitarism Associated with Chromophobe Tumor.**—Hurxthal and Younghusband say that a presumptive diagnosis of chromophobe tumors rests on the finding of an enlarged sella and evidence of visual change or hormonal deficiency, or both. They believe all enlargements of the sella turcica should be considered due to some abnormality whether or not there is clinical evidence of secondary effects. They regard chromophobe tumors as much more frequent than is generally believed, pointing out that in some cases there may be no hormonal change as long as there is sufficient normally functioning pituitary tissue. In others, there may be only mild degrees of pituitary failure, while in some there may be evidence of almost complete failure. Today there are numerous tests which are of great help in detecting these hormonal deficiencies, especially when clinical evidence is equivocal. The authors mention the various tests of hormonal deficiency: those involving the thyroid, adrenal and gonadal functions and those concerned with the carbohydrate metabolism. They feel that these tests should be carried out whenever enlargement of the sella is found. Visual field examinations and determination of visual acuity should be done in all cases in which the sella is enlarged. The authors emphasize the importance of a careful history and discuss the variable and somewhat contradictory findings in patients with chromophobe tumor. Roentgen treatment rarely restores normal pituitary function. Pituitary extracts are not satisfactory, although temporary effects have been observed after administration of thyrotropic and chorionic gonadotropins. Adrenocorticotropic extract is not effective if hypopituitarism exists. Two synthetic substances have proved effective and convenient. These are testosterone and desoxycorticosterone. Desiccated thyroid in doses of not over 1 grain (60 mg.) a day may be used, but the authors advise against the use of estrogens, because they suspect that estrogens may stimulate chromophobe tumor growth.

**Pineal Tumors.**—According to Horrax pineal tumors are among the rarer forms of intracranial new growths. During recent years it has been realized that certain of them respond extremely favorably to either operative or roentgen therapy, or at times to a combination of the two. He reviews observations on the 22 patients in whom the diagnosis of pineal tumor has been made. In 14 instances this diagnosis was verified at operation or at necropsy. In the other 8 patients the diagnosis has been made by the combination of localizing neurologic signs confirmed by the ventriculographic evidence of a mass projecting into the posterior portion of the third ventricle. Of the 22 patients there were 10 who had grossly complete operative removal of their tumors. Four of these operations were undertaken because decompression followed by roentgen treatment had failed. Three patients in this group of 10 are alive and well, ten, five, and three years after the operation, respectively. Twelve patients have been subjected to a simple decompression or a biopsy of the tumor. Those who survived have been given deep high voltage roentgen therapy. Four patients in this group have had their tumors verified histologically, while the diagnosis in the other 8 rests on the neurologic and ventriculographic findings. In this group of 12 there are 7 patients who have been alive and well from two to fifteen years. Three of them have moderate diabetes insipidus. One other patient had decompression and therapy only three months ago. Her pressure symptoms have not yet subsided. The remaining 4 patients died within a few days to a year after their operations.

**Histoplasmin Sensitivity.**—Seastrunk and Cullum tested 1,000 patients, 514 men and 486 women, with histoplasmin intradermal antigen at the Richland County Tuberculosis Clinic in Columbia, S. C. Thirty-nine of the patients tested were observed to be positive reactors (3.9 per cent). There were about 1.5 per cent more reactors in the white patients than in the Negroes, and 1.5 per cent more reactors in men than in women. There were no positive reactors between the ages of 1 and 5 years; there was 1 positive reactor among 76 patients between the ages of 6 and 10 years, 7 positive reactors in 465 patients between the ages of 11 and 20 years and 31 positive reactors in 438 patients aged over 21. Each of the 1,000 patients received a tuberculin test. There were 413 positive tuberculin reactors as compared with the 39 positive histoplasmin reactors. Thirty patients had positive reactions to both histoplasmin and tuberculin. Pulmonary calcification was present in 13 of the 39 positive histoplasmin reactors, while only 10 of the 413 positive tuberculin reactors presented pulmonary calcification. Histoplasmosis should be considered in the differential diagnosis of pulmonary diseases resembling tuberculosis in patients with negative sputum and negative tuberculin reactions.

*Carcinoma of Cervix—Review of 100 Cases. E. M. Baker.—p. 29.
Abnormal Vaginal Bleeding. G. S. Edgerton.—p. 37.

**Carcinoma of the Cervix.**—Baker reports 100 patients with cancer of the uterine cervix. According to the League of Nations Classification, 11 belonged to group I, 18 to group II, 22 to group III and 49 to group IV. A combination of intracavitary cone roentgen radiation, external roentgen radiation and radium was given to 46 of the patients, with 19 (45 per cent) surviving five years or longer. Combined intracavitary and external roentgen radiation was applied to 26 patients, with 8 (31 per cent) surviving five years or longer. Three patients were treated with radium alone, and 2 of the 3 lived five years or longer. Three patients with stage I carcinoma were treated with a combination of radium and surgery with a 100 per cent five year survival. The cornifying and the noncornifying squamous cell carcinomas showed the same five year survival rate—i. e., 26 per cent. Seven of 21 patients (33 per cent) with stage IV carcinoma treated with combined intracavitary and external roentgen radiation survived five years, while only 2 of 15 patients (13 per cent) in this stage survived five years when treated with radium, intracavitary roentgen radiation and external roentgen radiation. Thirteen of the 100 patients in whom the cervical cancer was completely destroyed, leaving no local evidence of the disease, succumbed to metastases two to five years following the initial treatment. Autopsies revealed that radium is contraindicated in pelvic inflammatory disease; the cachexia observed was out of all proportion to the extent of malignant tissue; the degree of cachexia and the degree of anemia bore no direct relation to the amount of radiation used. Metastasis occurred most frequently into the cervical parametrium and into the vaginal mucosa. Hydroureter and hydronephrosis occurred in about 70 patients due to ureteral compression, scar tissue and tumor.

**New Diuretic in Myocardial Failure.**—Herrmann and associates report their experiences with thiomerin® (disodium salt of N[gamma-carboxymethyl-mercaptomercuri-beta-methoxy] propyl camphoramine acid). They injected thiomerin® subcutaneously in 100 cardiac patients and intravenously in 50 patients. The drug was given in 2 cc. doses subcutaneously for five days in succession. Some patients have had as many as twenty 2 cc. subcutaneous injections of thiomerin® without untoward effects. The authors believe that the compound has advantages over the older organic mercurials. It is less toxic and less irritating. It is the only organic mercurial diuretic that is tolerated in the subcutaneous tissue; it must not be injected into edematous skin or adipose tissues. It may be used as a test in from 0.25 to 0.5 cc. doses subcutaneously in any patient suspected of hypersensitivity to mercury. The diuretic potency is at least comparable to that of the older preparations. It is generally less dramatically dehydrating on the first day but more persistent in effect for two or three days. Acid salts augment the diuretic action to the point that half or less doses, 0.5 to 0.75 cc. (20 to 30 mg.), are effective. Electrocardiographic studies after an injection of thiomerin® showed no changes in conduction or significant changes in rhythm. Only in 3 patients were occasional premature contractions recorded. Studies revealed evidences of renal irritation in a few instances, but not any more than after the use of other mercurials. Thiomerin® has been given on five successive days without producing albuminuria, cylindruria or hematuria.

**Vascularization of Human Stomach: Shunting Effect of Trauma.**—Barclay and Bentley say that in the course of an investigation into the blood vessels of the ulcerated stomach it became evident that the circulation through the gastric vessels is modified as a result of surgical operation. The mucous membrane of stomachs removed at operation is excluded from the active circulation in the stomach wall, further studies indicating that this is brought about by an arteriovenous shunt, similar to that described in the kidney. The authors describe experiments during which radiopaque substances were injected at pressure into the arteries of the stomach excised for duodenal ulcer or removed from a cadaver. Their observations indicated that there is an arteriovenous anastomosis or shunt located in the submucous plexus. Observations were made also in the course of operations. The authors deduce from their studies that there are arteriovenous anastomoses in the region of the submucous plexus of vessels, the opening of which excludes active circulation through the vessels of the mucous membrane. When the peritoneal cavity is opened and the stomach handled at operation the shunt comes into play, and this condition persists in the excised stomach wall after the operation. There is some evidence indicating that the arteriovenous anastomoses in the stomach wall are under the control of the autonomic nervous system, for when the sympathetic outflow to the stomach is blocked by means of spinal anesthesia the shunts do not open, and injection of the stomach vessels reveals complete filling of the extensive blood supply of the mucous membrane. In an editorial comment on these investigations, Alvarez, in the same issue, suggests that the shunt appears to be opened up under nervous stress. Such a mechanism could explain the sudden formation of peptic ulcers and especially of the acute penetrating or perforating ulcers which are seen so commonly in persons who die with a brain tumor or after an operation on the brain or an operation on a highly toxic goiter. Perhaps now a cure for ulcer can be secured if some way can be found of denervating this shunt.

1:333-378 (Feb. 26) 1949

Pain in Childbirth: Report of Subcommittee of Medical Women's Federation; Statistical Analysis of Some Replies to Questionnaires. K. K. Conrad.—p. 333.
*Tuberculous Meningitis: Early Diagnosis, and Review of Treatment with Streptomycin. J. Rubie and A. F. Mohun.—p. 338.
*Nasal Carriers and Streptococcal Tonsillitis. G. T. Cook and D. Munro-Ashman.—p. 345.
Spontaneous Perforation of Esophagus: Surgical Repair, with Recovery. J. Scholefield.—p. 348.
Rupture of Intestine Due to Non-penetrating Injury: Unusual Accidents from Mechanical Saw. H. L. M. Roualle.—p. 350.

**Tuberculous Meningitis.**—Rubie and Mohun analyze the clinical and laboratory aspects of 76 patients, in 67 of whom a diagnosis of tuberculous meningitis was made. The remaining 9 patients, who recovered without streptomycin therapy, included 5 tuberculous subjects with a meningeal reaction who may have had serous tuberculous meningitis. Observations of the 9 patients prove that patients may present a history of contact with tuberculosis, with evidence of extrameningeal tuberculosis, and with abnormal cerebrospinal fluid, and yet may not have what is ordinarily regarded as tuberculous meningitis. Mental apathy is an important early diagnostic feature. In 3 cases of tuberculous meningitis the cerebrospinal fluid was normal in the earliest stage in spite of clinically suggestive features. Diagnostically important cerebrospinal fluid changes are fall in sugar, rise in protein and pleocytosis. Prior to and within forty-eight hours of admission acid-fast bacilli were seen in the cerebrospinal fluid in 39 cases. Mycobacterium tuberculosis was recovered by culture and/or guinea pig inoculation in 58 cases. Diagnosis by one or both of these criteria was established in 62 cases. The scheme of streptomycin therapy followed by the authors is: intrathecal and intramuscular treatment, 28 days; intramuscular treatment, 28 days; intrathecal and intramuscular treatment, 28 days; rest period of 28 days, and intramuscular treatment only, 28 days. The intramuscular dose is 0.02 Gm. per pound (0.45 Kg.) of body weight in twenty-four hours, given every six hours. The intrathecal dose is 0.1 Gm. in 10 cc. of isotonic sodium chloride solution daily. Further treatment is given subsequently if indicated. Reviewing the results of this treatment of 54 patients followed up for a minimum of eight months, the authors say that 18, or one third, survived, 16 of them showing complete clinical recovery. Two survivors had a history of relapse and showed definitely abnormal cerebrospinal fluid. Ten patients were operated on for relief of hydrocephalus. While surgical intervention seems to offer a logical approach to the relief of the hydrocephalus, the results have been disappointing. Only 1 of the 10 patients thus treated survived, but in other cases life was prolonged. Early diagnosis and good nursing are important factors.

**Nasal Carriers and Streptococcal Tonsillitis.**—The outbreak of tonsillitis described by Cook and Munro-Ashman involved 57 out of 340 boys, who were housed in five separate buildings. The pattern of the daily incidence of new infections suggests that the epidemic spread fairly rapidly through a house during the three weeks after the return of H., a heavy nasal carrier. During the first eighteen days after the return of H., 17 new cases occurred among the boys in dormitories and 9 among those in single rooms, the number at risk being 47 and 85, respectively. Thirteen of the 17 dormitory cases occurred in three dormitories where 27 boys were at risk. It is clear that during this time boys in dormitories suffered more heavily than the others and that most of the cases came from three of the six dormitories. Streptococci of the epidemic type were isolated from the dust before the majority of dormitory infections had occurred. In addition to the possibility of infection being transmitted more or less directly from the carrier, the dormitory population was thus also exposed to the further risk of a heavily infected environment. Experience of this and other epidemics has shown the frequent association of heavy nasal carriers with outbreaks of streptococcic tonsillitis in residential schools. Nasal as well as throat swabs should be obtained in all cases, however mild the disease; heavy nasal carriers should be treated until their swabs are negative. This is especially necessary in the early stages of an outbreak before widespread contamination of the environment and the build-up of a carrier rate has occurred.

# Book Notices

**Lung Dust Lesions Versus Tuberculosis.** By Lewis Gregory Cole, M.D., F.A.C.R. Cloth. Price, $10. Pp. 474, with illustrations. American Medical Films, Inc., 8 Church St., White Plains, N. Y., 1948.

This work is a contribution to the frequently perplexing subject of the differentiation between the lesions of the pneumonoconioses, such as silicosis, and those that result from other causes, particularly tuberculosis. The author's approach as discussed in the preface is essentially that of exhaustive study of pathologic and roentgenologic material correlated with personal occupational and clinical histories when possible, or those of others when personal examinations could not be arranged. His main aims are (1) to correlate pathologic and radiologic data, (2) to describe and illustrate radiologic findings and interpret them into radiologic diagnoses, (3) to identify pulmonary lesions of dust origin as distinguished from those of tuberculosis and (4) to facilitate thereby the equitable settlement of medicolegal questions of concern to both management and labor. He makes no claim that any of his investigations are original, but points out that some of the observations may not be familiar to many others in this field.

The author presents a synopsis of the problems encountered in an exploration of the subject, pertinent to the industrial physician, the radiologist, pathologist, petrologist, physicist and x-ray technician.

As a basis for his studies an extensive collection of gross specimens, microscopic sections and roentgenograms was assembled from a wide range of sources in this country and Canada through the cooperation of roentgenologists, clinicians and pathologists. The text is liberally illustrated with halftone cuts in black and white. The running captions describing the figures are printed in bold face type. A characteristic feature of the book is the wealth of this material, affording a comprehensive coverage of various types of lung dust lesions compared to those of tuberculous origin. The pathology of lung dust lesions is considered under six types, illustrated with schematic drawings and roentgenograms correlated with pathologic appearances.

Two chapters of outstanding interest merit special mention; one dealing entirely with the roentgenologic diagnosis of lung dust disease as differentiated from tuberculosis, and another concerned with combined dust and tuberculous lesions (silicotuberculosis). This work is a valuable addition to the literature of the pneumonoconioses and should serve as a highly useful source of information for industrial physicians, roentgenologists and pathologists confronted with the problems of the differential diagnosis of silicosis or other dust diseases.

**Biological Reactions Caused by Electric Currents and by X-Rays: A Theoretical Study of the Phenomena of Excitation in the Nerve by Different Electric Currents and of the Biological Reactions Caused by X-Rays, Both Based Upon a Common Principle.** By J. Th. van der Werff, M.D., D.Sc. Cloth. Price, $5. Pp. 203, with 38 illustrations. Elsevier Pub. Co., 215 4th Ave., New York 3, 1948.

Seldom does one find a physician who is at the same time a mathematician and a physicist. When one recalls the startling discoveries made in the field of physics with the help of mathematics—e. g., Einstein's derivation of the relation between energy and mass—it is reasonable to believe that through the medium of mathematical deduction things unknown in biologic and physiologic processes might be discovered.

This volume is a mathematical treatise on biologic and physiologic problems. Two subjects are discussed: (1) "the phenomena of excitation caused by electric currents and especially those of excitation of the nerve," and (2) "the biological reactions caused by x-rays are analogous to such an extent that it is highly probable that they may be explained from a common principle." The book is in three parts: part I, General Introduction and Essentials; part II, Electrical Excitation of the Nerve, and part III, Biological Reactions Caused by X- and Y-Rays. It contains many diagrams, charts and formulas.

A general practitioner, unless he is well versed in calculus and differential equations, will not get much out of the book. This volume is especially recommended as a reference for the research man, mainly in the fields of biophysics and radiology.

**Modern Pattern for Marriage: The Newer Understanding of Married Love.** By Walter R. Stokes, LL.B., M.D. Cloth. Price, $2.25. Pp. 143, with 4 illustrations. Rinehart & Co., Inc., 232 Madison Ave., New York 16, 1948.

In recent years, books relating to marriage and sex problems have appeared in such large numbers that another would seem unnecessary. This statement, however, does not hold true for "Modern Pattern for Marriage" by Walter R. Stokes. This book should go a long way toward saving many marriages.

Dr. Stokes has given the theme for his book in the dedication, which reads, "Dedicated to the elimination of superstition and fear from our sex life and to the development of more realistic patterns for finding and conserving happiness in marriage."

According to Dr. Stokes, healthy attitudes about sex which are essential to a happy marriage literally begin at birth. While he believes that nearly all human beings are born with the instinctual and intellectual capacity for a successful marriage, he is convinced that the manner in which instinct and intellect are guided throughout childhood will determine whether this will be achieved.

Throughout the entire book, which is packed with important factual information about every aspect of marriage, Dr. Stokes has presented his material in such an objective, common sense manner that the reader is bound to assimilate some of his sane and sensible philosophy of marriage. This, it seems, is the major contribution of the book and the feature which makes it stand out from other books in the field.

The important topics covered in the different chapters of the book include the anatomy and physiology of sex, premarital sexual habits and experiences, premarital medical counsel, the honeymoon, problems of early and later marriage, and guiding children toward a sane marriage. There is an excellent glossary of technical terms, a list of books and publications on marriage and family life, and one of national organizations concerned with the problems of marriage and the home.

**British Surgical Practice.** Under the General Editorship of Sir Ernest Rock Carling, F.R.C.S., F.R.C.P., Consulting Surgeon, Westminster Hospital, and J. Paterson Ross, M.S., F.R.C.S., Surgeon and Director of Surgical Clinical Unit, St. Bartholomew's Hospital, London. In Eight Volumes (With Index Volume). Volume 4: Facial Palsy to Hiccup. Cloth. Price, $15. Pp. 486, with 263 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3; Butterworth & Co., Ltd., 4-6 Bell Yard, Temple Bar, London, W.C. 2, 1948.

The fourth volume in the excellent series covers subject matter from facial palsy to hiccup. Facial palsy as caused by trauma during mastoid operations is given prominence. The operation for mastoiditis is performed infrequently when compared with former years. More emphasis might be placed on injury to the seventh cranial nerve and its branches in operation for high cervical lymph nodes.

Gallie's article on fascial grafts is good and will appeal to the surgeon. Fibrositis is another well discussed topic. The subject of fractures and dislocations is covered briefly, but the discussion appears to be adequate. Gout, gonorrhea, foot surgery, hand surgery, gallbladder surgery and gastrocolic fistula are other topics. Much space is devoted to repair of hernia. Many related subjects necessary for adequate criticism will be dealt with in succeeding volumes. Thus far the objectives of the publishers and editors seem to be fully obtained. The praise of preceding volumes is extended to this one.

**Social Medicine: Its Derivations and Objectives.** Edited by Iago Galdston, M.D. The New York Academy of Medicine, Institute on Social Medicine, 1947. Cloth. Price, $2.75. Pp. 294. Commonwealth Fund, Division of Publications, 41 E. 57th St., New York 22; Oxford University Press, Amen House, Warwick Sq., London, E.C. 4, 1949.

By sponsoring an Institute on Social Medicine in connection with its Centennial Celebration in 1947, the New York Academy of Medicine courageously advanced into a vast territory badly needing thorough exploration through teamwork. The papers read at that time, together with introductory remarks by the three physicians primarily responsible for the organization of the institute, form the content of this notable book.

The rapid advance of scientific medicine and the profound socioeconomic changes that have taken place since the nineteenth century have led not only to the rediscovery of old modes of thought and their reappraisal in the light of modern concepts but also to the study of long-known methods of social action and the evaluation of their merits and applicability under present conditions. Social medicine is a living concept, but its objectives, content, place among the scientific disciplines, methodology and relationship to such fields as preventive medicine and public health are far from clearly defined. At present the term social medicine is used to denote some or all of the following subject matters: the bearing of socioeconomic conditions on the health of the individual and the community; the effect of illness on the socioeconomic conditions of the individual, family, community and nation; the importance of socioeconomic methods to the prevention of disease and the reduction of its frequency and severity, and the organization and administration of health service and medical care programs.

Directly or indirectly all these subjects receive attention in this carefully edited, systematically arranged and well printed book which embraces the labors of many men from widely diversified fields of experience. The broad ramifications of what is interpreted as social medicine become apparent, much useful information is imparted and a forceful argument is presented for more orderly study of the many intricate problems involved as well as for more systematic coordination of effort.

**Techniques of Histo- and Cytochemistry: A Manual of Morphological and Quantitative Micromethods for Inorganic, Organic and Enzyme Constituents in Biological Materials.** By David Glick, Ph.D., Associate Professor of Physiological Chemistry, the Medical School, University of Minnesota, Minneapolis. With a foreword by Robert R. Bensley, M.B., D.Sc. Cloth. Price, $8. Pp. 531, with 159 illustrations. Interscience Publishers, Inc., 215 4th Ave., New York 3, 1949.

This long-awaited book on an advancing field embracing many overlapping sciences will satisfy a need felt by biochemists, physiologists and morphologists. It consists largely of selected technical procedures described in the literature dealing with both the descriptive and quantitative aspects of the subject. The greater part of the book is devoted to quantitative methods, and these are well treated, particularly those developed by the Carlsberg Laboratories in Copenhagen.

The section dealing with descriptive methods involving only localization of substances in cells and tissues could be greatly improved, both as to selection of methods and as to a discussion of principles involved. This part of the book is surpassed by the more critical but outdated book by Lison. The section dealing with deductive methods is inadequate in view of important contributions made with them. Omitted almost entirely is a consideration of methods employed in elucidating the molecular structure and organization of cells.

A serious question that the writer of any advanced textbook on technics must face is whether the methods employed may be separated from a consideration of results obtained through their use. The extent to which this was practiced in this book may perhaps constitute a weakness. However, as reference is made to over six hundred titles in the literature, this objection may not be so important. The book is well printed, with numerous clear line diagrams and drawings and with a considerable amount of clear space for notes.

**Medical Statistics from Graunt to Farr.** By Major Greenwood, D.Sc., F.R.C.P., F.R.S. The Fitzpatrick Lectures for the Years 1941 and 1943, Delivered at the Royal College of Physicians of London in February 1943. Cloth. Price, $2. Pp. 73. The Macmillan Company, 60 Fifth Ave., New York 11; Cambridge University Press, Bentley House, 200 Euston Road, London, N.W. 1, 1948.

Doctor Major Greenwood traces the history of vital statistics and medical statistics from the early contributions of John Graunt and Sir William Petty in the seventeenth century to the time of William Farr in the nineteenth century. The development of the earliest life tables and the introduction of the collection of vital statistics occurred in this interval. The enumeration of populations was developed as a result of the works of these early pioneers in medical statistics. While the methodology of the times was exceedingly meager, the fundamental problems of vital statistics were sufficiently realized that the concept of standardized death rates was introduced. Greenwood's writing follows an essay style and is particularly noteworthy for its evaluation of the contributions of the early investigators on the basis of their personality. This book is not mathematical and could be enjoyably read by any physician.

**The Treatment of Pneumococcic Pneumonia in the Adult.** By Morris F. Collen, M.D., Director, Department of Medicine, Permanente Foundation Hospital, Oakland, Calif. Cloth. Pp. 166, with 40 illustrations. Permanente Foundation, 1924 Broadway, Oakland 12, Calif., 1948.

This book is a thorough compilation and critical analysis of experience with the treatment in 3,000 cases of pneumococcic pneumonia at the Permanente Foundation Hospital at Oakland between the years 1942 and 1947. All phases of the specific and general therapy of the patients are discussed and authenticated by presentation of data from this experience. The clinical aspects of the disease are also presented and include the various types of complications of the pneumonia as well as the various predisposing factors and complications due to underlying diseases in the patient. The management of these complications and their effect on the prognosis are also discussed and authenticated by analysis of the results of the experience in the series of cases presented. Individual cases are frequently cited to illustrate important points. There are numerous tables simply arranged, and also many clear graphic charts demonstrating the points that the author discusses.

The book is well bound and clearly printed on good paper which has permitted fine reproduction of roentgenograms and photographs. There is also an index and a bibliography of 179 references, many of them, of course, to the papers published by the author and his co-workers during the course of the accumulation of material which is summarized in this volume. The book will be read with considerable interest by all internists and is a useful addition to the classical volumes on pneumonia by Bullowa, Reimann and Heffron.

**Changing Disciplines: Lectures on the History, Method and Motives of Social Pathology.** By John A. Ryle, M.D., Professor of Social Medicine in the University of Oxford, Oxford. Oxford Medical Publications. Fabrikoid. Price $3.75. Pp. 123, with 13 illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London E.C. 4, 1948.

The author is the head of the Institute of Social Medicine at the University of Oxford. The lectures here included were developed for the New York Academy of Medicine and the Johns Hopkins Medical School. As a pioneer in the organization of education in the field concerned, all that Professor Ryle has to say is of interest to the physician. Among the most interesting of the essays is that dealing with medical ethics and the new humanism, since it provides opinions and information on problems that are today rather controversial. One finds Dr. Ryle saying that the decline in infant mortality can be attributed in large part to general social betterment and the falling birth rate, whereas Sir Stafford Cripps recently gave most of the credit in Great Britain to nationalization of medicine.

**Hutchison's Food and the Principles of Dietetics.** Revised by V. H. Mottram, M.A., and George Graham, M.D., F.R.C.P., Consulting Physician to St. Bartholomew's Hospital, London. Tenth edition. Cloth. Price, $6.75. Pp. 727, with 28 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

This tenth edition of a work well established in Great Britain represents an extensive revision with the addition of much new material. The sections on obesity, diseases of the liver, rickets and scurvy have been revised, and the authors have apparently considered it worth while to make a scientific criticism of the Hay diets, which by this time arouse little or no interest in the United States, where they were concocted. The Hay diets are included with such other peculiar concoctions as vegetarian, fruit and raw vegetable, exclusive protein, meat juice and similar diets. The authors say that they do not propose to give any details of these diets as they can say unhesitatingly that they are dangerous.

**Essays on Historical Medicine.** By Bernard J. Ficarra, A.B., Sc.B., M.D., Professor of Research Biology in Charge of Experimental Physiology, St. Francis' College, Brooklyn, N. Y. Cloth. Price, $5. Pp. 220, with illustrations. Froben Press, Inc., 1776 Broadway, New York 19, 1948.

Most of the essays in this book were prepared for reading to medical organizations, and their central theme is surgery and pathology. Among the most interesting of all of the essays is one called "Famous Autopsies in History," previously in the *Annals of Medical History*.

**The Diagnosis of the Acute Abdomen in Rhyme.** By Zeta. Second edition. Cloth. Price, 6s. Pp. 93, with drawings by Peter Collingwood. H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C. 1, 1949.

The author's objective in this book of rhyme is to amuse while he tries to teach. He does not claim to be a poet; neither is he a professional humorist. However, the line drawings by Peter Collingwood are clever and humorous. The subjects about which the author endeavors to rhyme are intestinal obstruction, ectopic gestation, peritonitis, pancreatitis, colic, acute dilatation of the stomach, and treatment. The trend of his rhyme is toward problems of diagnosis and pathology. For example:

True renal colic one can soon decide
For all the pain is felt on the one side
And when you come to make examination
The kidney may be tender on palpation,
While pain may radiate to—inter alia—
The iliac region or the genitalia;
And here, although the caution somewhat trite is,
Remember renal colic on the right is
Oft taken for a plain appendicitis.
A specimen of urine you must see
And look if blood or gravel there may be,
Nor must you fail to make interrogation
For frequency and pain on urination.
*Thus soon will you make up your hesitating mind*
*And renal colic as the diagnosis find.*

* * * * *

Now biliary colic is a terrible complaint
The pain is so severe that oft the patient feels quite faint;
'Tis felt around a zone served by the nerves 8 and 9 D
Which roughly means the place where your pyjama cord should be.
In fact I've oft been told that when the pain is at its height
It feels as if that cord were tied immeasurably tight.

A smoother group of lines follows his attempt to teach the subject of ectopic gestation:

In seeking for his mate the eager sperm
Up the fallopian tube his way doth worm
And in that narrow channel often meets
The lovely ovum whom with joy he greets
And soon the happy union completes.
The embryonic cell now grows apace
Within the cramped and so secluded space,
Still microscopic it is moved along
*By cilia of the cells it stands among;*
Sometimes however from some mystic causes
The ovum in its onward passage pauses
And grows so big that there it must be nursed
Until it die or tragically burst.
To this condition—one or other side—
Tubal gestation is the term applied.

The author makes no claim that what he writes will merit fame; nor is he proud of this endeavor for in using Zeta his true name he hides forever.

**Pioneer Life in Kentucky 1785-1800.** By Daniel Drake, M.D. Edited, from the Original Manuscript, with Introductory Comments and a Biographical Sketch by Emmet Field Horine, M.D. Cloth. Price, $4. Pp. 257, with illustrations. Henry Schuman, 20 E. 70th St., New York 21, 1948.

The first edition of this book was published in 1870. It has been reprinted once. Its quality as a contribution to medical history is of the highest. With every new bit of information relative to Daniel Drake, his stature rises. He was one of America's greatest pioneer physicians. His two volume work "Principal Diseases of the Interior Valley of North America" is a medical classic. Daniel Drake was the first medical student of Cincinnati. He gave Ohio the name of Buckeye state. He was a professor in several medical schools and the founder of an early medical journal.

**Psychiatry for the Millions.** By Benzion Liber, M.D., Dr.P.H., F.A.P.A., Professor of Psychiatry and Director of the New York Mental Hygiene Clinic at Polyclinic Hospital, New York. Cloth. Price, $2.95. Pp. 307. Frederick Fell, Inc., 386 Fourth Ave., New York 16, 1949.

The blurb for this work asserts that it "discusses every facet of the human mind and the problems that beset it." At present the American market is simply flooded with "don't worry" books. This one is rather technical and certainly suited to the medical rather than the lay reader. Its interest is bolstered by some case reports. Altogether the book is loosely assembled. Many of the cases seem to be much too simply solved. There are 10 or 15 pages of small type indicating how a schizophrenic person thinks—material which cannot be of any real value or perhaps even interest to the average reader.

**The Surgery of the Stomach and Duodenum.** By T. H. Somervell, M.A., M.B.; B.Ch., Surgeon-in-charge, London Mission Hospital, Neyyoor, S. India. Cloth. Price, $11. Pp. 546, with 231 illustrations. Williams & Wilkins Co., Mt. Royal and Guilford Aves., Baltimore 2, 1948.

This book was prompted by the situation of the author in an area where gastric and duodenal lesions are rife. He has worked for over two decades in a mission hospital in South India. He has also thoroughly combed the literature, and quotes liberally from many sources. Whenever the material is from his own clinics, the text is refreshing and interesting. Too often the author buries his observations in the midst of many opinions from other authorities. He does use the figures of others for comparison purposes. Thus, his observations on the incidence of duodenal ulcer in his geographic area are extremely interesting.

Operative technics are more or less standard. Ligation of the vessels to the stomach is strongly advocated as a means of lowering gastric acidity. Such operations have previously been tried and abandoned in Italy and in this country. Nevertheless, 3,373 operations for duodenal ulcer in sixteen years represents a most concentrated and extensive experience. While Mr. Somervell's theories may not be agreeable to all, his observations are keen. Gastroenterologists, both medical and surgical, can profit from this book.

**Studies in Psychosomatic Medicine: An Approach to the Cause and Treatment of Vegetative Disturbances.** By Franz Alexander, M.D., and Thomas Morton French, M.D., with others. Cloth. Price, $7.50. Pp. 568. Ronald Press Company, 15 E. 26th St., New York 10, 1948.

This book represents a collection of papers published by the staff of the Chicago Institute for Psychoanalysis during the past sixteen years, and is based on the psychoanalytic studies of patients suffering from chronic disturbances of the vegetative organs.

With the present emphasis on psychosomatic medicine, a work of this type is especially valuable in correlating the underlying psychogenic disturbance with the somatic manifestation. It further strengthens the opinion that the analytic approach to these problems yields a more fundamental and rational basis than is possible by the ordinary psychotherapeutic measures currently employed. These various studies are classified according to the type of somatic disturbance, and this is of distinct value to anyone interested in a particular symptom or disease. Detailed patient analyses are presented in a readily comprehensive manner. Only occasionally does one find conclusions which do not seem to be wholly justified as determined by the material presented.

This work is especially recommended to internists who are faced with these problems in their every day practice, and it will be found to be a very excellent reference work in managing their patients with psychosomatic disturbances.

**Insect Pests.** By Wm. Clunie Harvey, M.D., D.P.H., F.R.San.I., Medical Officer of Health, Borough of Southgate, and Harry Hill, F.R. San.I., F.S.I.A., A.M.I.S.E., Provincial Milk Advisory Officer, Ministry of Agriculture and Fisheries. Second edition. Cloth. Price, $5. Pp. 347, with 27 illustrations. Paul B. Hoeber, Inc., 49 E. 33rd St., New York 16, 1948.

The bedbug, flea, louse, mosquito, cockroach and other pests which carry disease and are a nuisance to man are discussed in detail in this book. The second edition is even better than the first, with new chapters on mosquitoes and moths and on DDT. Methods for insect control are discussed in full, with educational measures for the public, including leaflets, articles for the press, exhibits, motion pictures and other demonstrations. Chapters on infestation of foodstuffs and human toxicology will be of interest to the physician.

**An Account of the Weather and Diseases of South-Carolina.** By Lionel Chalmers, M.D., Of Charles-Town, South-Carolina. London: Printed for Edward and Charles Dilly, MDCCLXXVI. [Printed through courtesy of *Mead Johnson & Company, Evansville, Indiana.*] Paper. J. I. Waring, M.D., 82 Rutledge Ave., Charleston 37, S. C., [1948].

These extracts from the two volume account by Dr. Chalmers supply a vivid, clearly worded picture of the ideas and practices which constituted American medicine two centuries ago. Nothing quite so sharply emphasizes the remarkable advances made by medical science as does perusal of the well written works of this physician, who was outstanding in his day.

**A Short Practice of Surgery.** Parts I, III, IV. By Hamilton Bailey, F.R.C.S., F.A.C.S., F.I.C.S., Surgeon, Royal Northern Hospital, London, and R. J. McNeill Love, M.S., F.R.C.S, F.A.C.S., Surgeon, Royal Northern, Mildmay Mission and Metropolitan Hospitals, London. With Pathological illustrations by L. C. D. Hermitte, M.B., Ch.B., Pathologist, Royal Infirmary, Sheffield. Eighth edition. Cloth. Price, £2.12.6 per set of five parts. Pp. 224, with 259 illustrations; 421-628, with 303 illustrations; 629-808, with 163 illustrations. Williams & Wilkins Company, Mt. Royal & Guilford Aves., Baltimore 2; H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C. 1, 1948, 1949.

The eighth edition of this work differs from its predecessors mainly in the fact that it will appear in five small volumes. This is apparently a very popular survey of general surgery, since it has undergone reprintings or revisions in almost every year of its existence.

While advances in surgical treatment have been remarkable, it does seem that most surgical conditions have been adequately described in previous issues. Thus, a comparison of the fifth edition with the present one reveals evidence of rewriting, but the differences are not impressive. Penicillin is acknowledged in the treatment of several infectious conditions. The Murphy drip for proctoclysis could now well be eliminated save for brief mention.

As in previous reviews, the sections now available reveal the same excellent clinical presentation as in earlier editions. There are more illustrations in color. Physicians who are not familiar with Hamilton Bailey's technic of presentation will enjoy making this acquaintance.

**The Ciba Collection of Medical Illustrations: A Compilation of Pathological and Anatomical Paintings.** Prepared by Frank H. Netter, M.D. Cloth. Pp. 222, with 192 illustrations. Ciba Pharmaceutical Products, Inc., Summit, N. J., 1948.

This volume of beautiful, colored anatomic and pathologic illustrations is reminiscent of the famous Spalteholz anatomic drawings, except that much of each of these pages is devoted to concise descriptions of the illustrations. Both types of material are exceptionally well done. Over a period of years, these illustrations have been presented to the medical profession as separate sets of plates in portfolio form. Their popularity led not only to the reprinting of many thousands each year but to the preparation of the present volume containing all of the plates available up through 1948. This work is being continued, and eventually an almost complete atlas of human anatomy and pathology will result. The artist, a graduate of New York University and Bellevue, for a time engaged in private practice. However, his talent for illustration, which became evident in early youth, continued to demand expression throughout his student days, when he illustrated medical books and articles. After an internship, the demand for his illustrations was such he realized that his career lay in this field. During the war he was responsible for illustrating many of the Army training manuals. The carefully written texts which accompany the illustrations were prepared by such well known physicians as Michael de Bakey, Jacob Buckstein, Charles F. Geschickter, Henry H. Ritter, Eli H. Rubin, Samuel A. Vest and the late Reuben A. MacBraer. In sponsoring this work, Ciba Pharmaceutical Products Incorporated has done graduate and undergraduate medical students a good service.

**Volumetric Analysis. Volume II: Titration Methods: Acid-Base, Precipitation, and Complex-Formation Reactions.** By I. M. Kolthoff, Professor and Head, Division of Analytical Chemistry, University of Minnesota, Minneapolis, and V. A. Stenger, Analytical Research Chemist The Dow Chemical Company, Midland, Michigan. Second edition. Cloth. Price, $6. Pp. 374, with 14 illustrations. Interscience Publishers, Inc., 215 Fourth Ave., New York 3, 1947.

The contents of this book are based on a German monograph published first in 1928 by the senior author. It has been brought up to date by a careful screening of many methods and only the more reliable procedures are included. Evaluation of the precision of the experiments is given. The book deals with acid-base, quantitative precipitation and complex-formation reactions. The arrangement of the methods is determined by the type of reaction involved and not by the field in which it may be applied, although directions are given for the analysis of many substances which are found in the industrial, pharmaceutic and agricultural fields.

**Post-Mortem Appearances.** By Joan M. Ross, M.D., B.S., M.R.C.S., Advisor in Pathology to the Ministry of Supply, London. Oxford Medical Publications. Fifth edition. Fabrikoid. Price, $2.75. Pp. 308. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E.C. 4, 1948.

This little book, of convenient pocket size, was designed to describe gross anatomic changes seen at necropsy which help to characterize the main pathologic conditions. In addition to a brief description of necropsy methods, sections are devoted to the general findings to be expected in the presence of metabolic and deficiency diseases, infections and diseases of specific organs. A useful section deals with problems of stillbirths and neonatal deaths. In the appendixes weights and measurements of organs, dates of ossification and principal bones and states of maturity of the fetus are useful additions. It was hoped by the author that the book would be of aid to physicians who may have to perform an occasional necropsy, as well as to beginning students who wish to specialize in pathology. This little book may well serve a useful purpose in every morgue as a convenient and inexpensive reference source.

**The Mentally Ill in America: A History of Their Care and Treatment from Colonial Times.** By Albert Deutsch. Second edition. Cloth. Price, $5.50. Pp. 555, with illustrations. Columbia University Press, 2960 Broadway, New York 27; Oxford University Press, Amen House, Warwick Sq., London, E.C. 4, 1949.

Before he became a columnist for *PM* and more recently the New York *Post*, Mr. Deutsch was trained in medical history under Sigerist and wrote more particularly in the field of history of psychiatry. The latest edition of his book traces the evolution of psychologic medicine and provides new chapters on psychosomatic aspects of physical disease and the national mental health act. The quality of the work has been recognized by leaders in psychiatry, and indeed it is hard to reconcile the scientific approach to medical problems of this book with most of what Mr. Deutsch writes on other aspects of medical care.

**Your Child or Mine: The Story of the Cerebral-Palsied Child.** By Mary Louise Hart Burton. In collaboration with Sage Holter Jennings. Cloth. Price, $1.25. Pp. 64, with illustrations. Coward-McCann, Inc., 2 W. 45th St., New York 19, 1949.

This booklet consists of six well written case reports of children with cerbral palsy. The work is simply and clearly written and describes realistically some of the problems which are encountered in the management of these chlidren. It is primarily intended for parents and laymen who might want to know how a child with cerebral palsy acts and looks. The book is well printed and illustrated with good photographs. A bibliography and a list of cerebral palsy associations and clinics are appended and woud greatly enhance the value of the book if they were more comprehensive. The book can be recommended as interesting reading for laymen and parents of children with cerebral palsy.

**Which Way Out: Stories Based on the Experience of a Psychiatrist.** By C. P. Oberndorf, M.D. Cloth. Price, $3.25. Pp. 236. International Universities Press, Inc., 227 West 13th St., New York 11, 1948.

The case books of psychoanalysts are full of drama. Dr. Oberndorf, who is clinical professor of psychiatry at Columbia University, has a skill in dramatic writing well above that of the average scientist. One can gain at least a smattering of modern psychoanalytic approaches to mental problems in these stories. For the layman they are better than most of the interpretative writing on the subject by doctors or professional scientific writers. Apparently none of these stories has previously been published elsewhere.

**"Miss U."** By Margaret Utinsky. Cloth. Price, $3. Pp. 172, with illustrations by G. G. Estill. Naylor Company, 918 N. St. Mary's St., San Antonio 6, 1948.

"This is the story of the heroism of Margaret Utinsky, who, against unbelievable and fantastic odds, for three years led an underground organization in the Philippines in a relentless and telling effort to aid American prisoners of war held by the Japanese." It is no work of art, but it is marked by sincerity. Doctors, colonels and sergeants testify to her courage and sympathy.

# Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

## DIET FOR ATHEROSCLEROSIS

**To the Editor:—A tall thin man, age 43, had his gallbladder removed five months ago. It contained several large cholesterol stones. Recovery was uneventful; six weeks ago he suffered his first attack of coronary occlusion with infarction. He does not have hypertension. How strict a low fat diet for atherosclerosis should I prescribe? Should meat and whole milk be omitted? What is the exact dosage of choline and of inositol that will be definitely decholesterolizing? What precautions should be observed in taking these drugs over long periods? M.D., Kansas.**

Answer.—Since the blood cholesterol level in most cases of familial hypercholesterolemia does not fall on dietary restriction, on administration of lipotropic agents such as lecithin, inositol, choline, methionine or on high protein diets, it is impossible to describe a regimen which can be guaranteed to alter the pace of atherosclerosis or be "definitely decholesterolizing." When a man of 43 has such a history, it is probable that his blood cholesterol is high; if his diet has been rich in eggs, butter and cream, all these items, as well as liver, brain, kidney, sweetbreads, whole milk and cheeses made from whole milk, should be omitted. Meat should be cut down to 5 or 6 ounces daily. If, after two months, blood cholesterol has not fallen to 200 mg. per hundred cubic centimeters, or less, the effect of a pure vegetarian diet, which is cholesterol free, could be determined, or choline, lecithin and inositol could be given in doses similar to those used as adjuncts in treating hepatic cirrhosis. If the basal metabolism is minus 20 per cent or lower, thyroid extract should be given, beginning with ⅛ grain (8 mg.) daily for two weeks, and doubling the dose each two weeks until the basal rate is normal or unpleasant symptoms appear. The highest tolerated dose may be continued indefinitely if the blood cholesterol falls. Diet has little effect on the hypercholesterolemia of hypothyroidism.

## TREATMENT OF UREMIA

**To the Editor:—What are the new treatments for uremia occurring in chronic nephritis? Is 50 cc. of 50 per cent dextrose intravenously of value for uremia? Harry R. Deane, M.D., St. Petersburg, Fla.**

Answer.—Treatment of uremia due to chronic nephritis is still based on the general principle that this syndrome is the complex resultant of a variety of disturbances, including azotemia, acidosis and other electrolyte imbalance (hypocalcemia, hypochloremia, hyperpotassemia or hypopotassemia), dehydration, anemia, hypertensive encephalopathy, gastrointestinal and serous membrane inflammation, cardiac failure, cutaneous irritation and central nervous depression. Under these circumstances there is not any single all-embracing treatment for uremia. Rather is it symptomatic, varying with the individual symptoms and signs.

The major therapeutic measures, therefore, consist of (1) adequate fluid intake, parenteral if necessary, to produce a urinary output of at least 1,500 cc. daily; (2) correction of electrolyte imbalance or deficiency by frequent estimation of serum levels; (3) correction of acidosis by the proper use of sixth-molar sodium lactate solution; (4) restriction of protein in diet, or as amino acids or human serum albumin parenterally to the minimum, about 0.5 Gm. per kilogram of body weight, with use of carbohydrate to furnish calories; (5) intravenous injections of human serum albumin in patients with hypoalbuminemia and intolerance for food to tide them over short periods of malnutrition; (6) cautious transfusions of 250 cc. of packed erythrocytes or whole blood, after careful cross matching whenever hemoglobin level falls below 60 or 70 per cent; (7) use of sedatives best tolerated by the patient and least likely to cause cutaneous eruption; (8) digitalization for cardiac failure, preferably with the drug less likely to accumulate and confuse the clinical picture in regard to nausea or vomiting, and (9) avoidance of any food, drug, laxative or strong enema capable of irritating the gastrointestinal tract.

The value of 50 per cent dextrose solution intravenously is largely caloric, apart from temporary circulatory stimulation. The resultant thrombosis of veins is a serious disadvantage.

## DIAGNOSIS OF ULCER

**To the Editor:—The patient is a white man, aged 26; he is 6 feet (182.9 cm.) tall and weighs 212 pounds (96.1 Kg.). Since the age of 12 he has suffered recurrently from peptic ulcer. To his knowledge, there has never been hemorrhage or perforation. I first saw him one week ago; present symptoms are the same as recurred with each "attack" of ulcer. They are (1) severe "heartburn" constant in the epigastrium; (2) a sense of great fulness in the chest and the upper part of the abdomen, and (3) moderate diarrhea (five to six stools a day). These symptoms have been persistent for several months; he has visited several physicians, has used bismuth subcarbonate, aluminum hydroxide, mucin and magnesium compound. Relief is obtained only when he eats "huge quantities" of food every hour and takes 2 to 3 tablespoons of bismuth subcarbonate or sodium bicarbonate every fifteen to twenty minutes. Roentgen observations are as follows: "The stomach is abnormally high, is twisted on its longitudinal axis and is partly inverted so that the pars media is high in the mid-epigastrium and the lower third of the stomach is higher than the duodenum. The fundus is constantly distended with an unusually large amount of air. There is considerable irregularity of the rugae throughout the stomach; however, a true intrinsic lesion is not demonstrable. The pyloric valve is almost completely patent, and the stomach empties with extreme rapidity into the small intestine. The bulb of the duodenum shows a constant defect in the lesser curvature, apparently a nonobstructive duodenal ulcer." In a telephone conversation, the radiologist told me that the usual amount of barium sulfate given had left the stomach before he made the fluoroscopic examination, and he expressed the opinion that the remarkably rapid emptying time was probably responsible for the symptoms and could be due to the ulcer or possible hypertrophic gastritis or endocrine disturbances. The patient told me that he passed all the barium sulfate per rectum within three hours of its administration. I would appreciate your suggestions as to therapy. M.D., New York.**

Answer.—This is a puzzling problem. Epigastric burning, especially when constant, is practically always a paresthesia in the skin and is not due to an ulcer. It is hard to explain the sense of fulness in the chest and upper part of the abdomen. The diarrhea could be understandable on the basis of an extremely rapid passage of material through the stomach and bowel.

The relief of pain from eating huge quantities of food every hour suggests either the presence of a poorly controlled ulcer or bulimia due to a minor psychosis. The taking of large amounts of sodium bicarbonate may have something to do with keeping up the diarrhea.

The peculiar appearance of the stomach suggests a partial rotation, but this is a rare condition. It suggests also a cyst of the pancreas or some lesion which is pushing the stomach upward. If present, such a mass should be felt on palpation. The great distention of the upper part of the stomach with air is rare. It seems usually to be due to some peculiarity which enables the patient to swallow large amounts of air with his drink. The best treatment for this is to teach the patient to put down a tube after each meal so as to let the air out. Then it does not have to go through the bowel. This is particularly advisable after the last meal in the evening. It may enable the patient to sleep. Such intubation cannot do harm.

It is conceivable that the rapid emptying of the stomach is due to its having been made highly irritable by the presence of an ulcer in the duodenum. It is rare, however, to see such rapid emptying.

It would be interesting to know whether the patient is highly neurotic or somewhat psychotic person with tremendously increased reflexes. It would be interesting to know whether he feels the distress of impending diarrhea the minute he eats. In some of these cases the sweat breaks out and the patient suffers from a "dumping syndrome." Often in these cases the knee jerks are tremendously exaggerated, and the patient will bloat within a few minutes after taking a glass of cold water.

The unfortunate thing is that drugs have not been found that will slow the progress of material through the small bowel. Even opium is likely only to cause spasm in the terminal ileum. Physostigmine salicylate, pilocarpine and neostigmine are not likely to do any good. The trouble is that, in an animal, in order to make a bowel as sensitive and irritable as this, one has to cut the extrinsic nerves.

Charcoal when wet does not absorb gas. Betanaphthol used to be given with the idea of killing off bacteria in the bowel and thus stopping fermentation, but it does not do this to any great extent. If one wants to kill bacteria in the bowel one should use drugs like phthalylsulfathiazole and succinylsulfathiazole. They kill bacteria and cut down flatulence.

No mention is made about the intractability of ulcer pain. If this person's syndrome is due to an acute ulcer or an ulcer penetrating into the head of the pancreas, one would expect him to be suffering much pain. If he is not, one possibility is that he is an insensitive type of person whom a dentist cannot hurt. If this be true, one would suspect the more that he has a highly irritating type of posterior penetrating ulcer. The decision whether or not to operate depends largely on the character of the patient's nervous system. If he is somewhat psychotic an operation should be put off as long as possible. If, however, before this syndrome appeared he was a normal, hard-working, sensible, happy man, surgical exploration would be justifiable. If he operates, the surgeon must feel back of the duodenum or he may easily miss the perforation and may report absence of ulcer.

## PUFFINESS UNDER EYES IN CHILDREN

*To the Editor:*—A number of children practically all under the age of 8 are moderately underweight and moderately anemic; the face is somewhat puffed, mostly around the eyes; pitting edema is absent; the skin color is pasty; renal function and bowel function are satisfactory; appetite is poor and the children are "picky"; weight and height remain some below average, and one has the feeling that the child should be a little heavier and taller, as judged by his parents and the other children in the family. In some I found an allergic background. Specimens of urine are normal and dilution-concentration tests reveal values within normal limits; urinary calcium is present. Blood cell counts show moderate anemia of the secondary type. Report of stool examination is negative. Roentgenograms of bones do not reveal pathologic changes. The children's spirit is satisfactory, as are their school records. Susceptibility to respiratory infections is increased; styes are more frequent than in the average. Scratch tests and elimination diets are unsuccessful. In cases in which urinary calcium was absent, an oral calcium preparation was given; urinary calcium appeared but the general picture remained unchanged. Vitamin-liver-iron preparations caused slight increase in appetite. Thyroid in guarded doses does not have any influence. Ultraviolet irradiation provided a tonic effect, but the puffiness did not disappear. Please suggest further treatment.

M.D., New York.

Answer.—The clinical picture presented involves children under 8 years of age who are moderately underweight, moderately anemic, with sallow skin, slight anorexia and, finally, with puffiness under the eyes. It is noted that susceptibility to respiratory infections is increased. Except for moderate anemia, the various laboratory procedures are negative. Therapy has been unsatisfactory.

In the diagnosis of this group of children, whose main symptom is a puffiness of the face particularly around the eyes, there are a number of considerations which might be of aid. One might ask whether this puffiness is hereditary, and whether other members of the family evidence the same symptom. This type of puffiness, of course, would not be outgrown.

While the author of this inquiry may be describing a new clinical entity, it is more probable that the puffiness noted in children in this age group is due to respiratory infections and secondary anemia. These children outgrow this condition. It is a common observation that some small children, particularly those from 3 to 8 years of age, seem to suffer an interminable number of respiratory infections, particularly during the winter months while they are at school. These infections produce a secondary anemia of a moderate nature, and a constant inflammation of the throat and nasal passages make their faces appear puffy under the eyes. At about 8 years of age or thereafter, these children seem to acquire an increased immunity or resistance; they have less frequent respiratory infections and outgrow puffiness of the face.

That the spirit of the children is satisfactory, as are their school records, is an important differential point, for were there any severe systemic illness causing the puffiness of the face as described, the children would act chronically ill and their school records would suffer.

Further diagnostic measures do not seem to be called for, as the condition is self limited.

As to treatment, any measure that would increase the general resistance, such as adequate balanced diet, with particular emphasis on food stuffs containing protein and iron, would be indicated. The added vitamin, liver and iron preparations should be of adequate potency and should be given for sufficiently long periods. As long as infection persists it is difficult to overcome secondary anemia. Depending on the local condition in the nose and throat, a course of oral penicillin might be indicated to clear up persistent infection. In some cases chronically infected tonsils and adenoids may have to be removed. The chronicity of the tonsillar infection may often be judged by the persistence of cervical glands at the angle of the jaw. Occasionally the use of a respiratory vaccine may increase resistance so that the cycle of repeated infection is broken for a period at least. The action of such a vaccine is probably of a general immunologic or nonspecific type.

## ULCER TREATMENT WITH CABBAGE JUICE

*To the Editor:*—A patient suffering from a long-standing (chronic) duodenal ulcer recently noticed this newspaper article: *New York Times*, January 13, 1949, "Cabbage Juice for Ulcers," original work done by Dr. Garnett Cheney of the Stanford Medical School. Please enlighten me as to the value of this treatment.

Walter H. Siegel, M.D., Mineola, N. Y.

Answer.—Cheney (Cheney, G.: *Calif. Med.* **70**: 10-15, 1949) treated 13 patients, giving them at least 1 liter of fresh uncooked cabbage juice a day. The reason for giving this was that in guinea pigs cabbage appeared to prevent the formation of ulcers due to histamine.

Cabbages were put in a juice press, and usually it took 2 Kg. of the raw vegetable to produce 1 liter of juice. The addition of celery juice made the cabbage juice more palatable. The last 3 patients treated were given a mixture of three parts of cabbage juice to one of celery juice. Salt and pepper and tomato juice should also be added. One in 3 of the patients had some abdominal distress and constipation, relieved by milk of magnesia. The juice was given 200 cc. at a time, five times a day. It was unpalatable if kept overnight.

In addition to the cabbage and celery juice a diet was given in which all of the food was cooked so as to destroy other sources of the supposed vitamin U.

The patients were kept in bed until pain stopped. They were allowed to smoke. They were given sodium bicarbonate and codein sulfate for the relief of pain, also sleep makers at bedtime, and milk of magnesia to relieve constipation.

Cheney depended much on the roentgenologists to tell him when the ulcer was healed and claimed that craters disappeared rapidly, often within two weeks. Many gastroenterologists would not care to trust to this method or this criterion of ulcer healing. There were six gastric ulcers and one jejunal ulcer, all of which were seen with the gastroscope to heal rapidly. Cheney stated that the "'anti-ulcer factor' is readily destroyed by heat." Wisely he pointed out that the results are as yet only suggestive, and more work must be done.

Since November 1948, a concentrate of cabbage fat prepared by Viobin Corporation of Monticello, Ill., has protected guinea pigs from histamin-produced ulcers, when fed in doses of 100 mg. a day for a 300 Gm. animal.

Naturally, the big question will be, whether the healed ulcers will stay healed any longer after this treatment than after other treatments.

## ACTION OF PROCAINE ON SULFONAMIDE COMPOUNDS

*To the Editor:*—(1) At a staff meeting it was said that the procaine which is part of procaine-penicillin inactivates sulfonamide compounds; it was said that 1 part procaine would inactivate about 1,000 parts of sulfonamide compound (any?). Is that correct? If so does it hold true for any form of procaine, e. g., for local or spinal anesthetic? (2) Several companies claim that their penicillin preparation in oil, with aluminum monostearate added, will produce blood levels of therapeutic consequence for periods much longer than twenty-four hours. What is the official opinion in this matter?

R. J. Kent, M.D., Savannah, N. Y.

Answer.—(1) Theoretically, the procaine in a procaine-penicillin combination might prevent action of sulfonamide compounds, but the effect would be slight. The mechanism is as follows: Procaine is slowly liberated from penicillin in the body by hydrolysis in the form of procaine base. The procaine molecule then splits into two parts, one of which is triethanolamine and the other para-aminobenzoic acid. The latter has been shown to have an antagonistic effect against sulfonamide compounds. The relative extent of this effect is determined by the concentration and distribution of procaine and its degradation products. A dose of 300,000 units of crystalline penicillin G-procaine contains about 119 mg. of procaine base. Blood levels indicate that hydrolysis of the salt requires at least twenty-four hours. Further time is needed for the enzymatic splitting of the procaine. The para-aminobenzoic acid would be generally distributed in the body for twenty-four hours or more, and the competitive effect against sulfonamide compounds would be small. Procaine from other sources would act the same, but the effect would be dependent on usage and concentration.

(2) The addition of aluminum monostearate to procaine penicillin in oil has been shown to prolong the duration of assayable blood levels of penicillin. Robinson and associates have shown that intramuscular doses of 300,000 units result in assayable levels (0.03 unit per cubic centimeter, or more; formerly called "therapeutic blood level") in all patients at 120 hours. There were high levels at 24 to 96 hours, and 42 per cent had assayable levels at 144 hours.

The "official" aspect is also definite, since the Food and Drug Administration requires the manufacturer of antibiotics to provide protocols for any claims for a product which gives assayable blood levels up to 96 hours. There can be some variation, however, due to such factors as complete bed rest (ambulation hastens absorption) and methods of assay.

## TOXICITY OF MERCURY COMPOUNDS

**To the Editor:**—What is the toxicity of phenylmercuric borate? A dentist and a dental technician both consulted me at about the same time regarding epigastric pain, lethargy, easy fatigue and pallor. Both had a moderate secondary anemia and tenderness to pressure over the liver margins. They were using a cold sterilizing solution containing the named chemical. Both have improved since discontinuing its use. Is there any test delicate enough to show mercury in the blood?

Thomas S. White, M.D., Millbrook, N. Y.

Answer.—The toxicity of phenylmercuric nitrate and phenylmercuric chloride has been studied by Weed and Eckert (*J. Infect. Dis.* 52: 354, 1933). They administered the compounds orally to mice, rats and guinea pigs, intraperitoneally to mice and rats and subcutaneously to rabbits. They found that despite the high bactericidal action of these salts, they were relatively nontoxic when given orally, intraperitoneally or subcutaneously.

Isotonic phenylmercuric chloride was used to irrigate the bladders of rabbits, and it was found to give less inflammatory reaction than did saline solution. A lethal dose of phenylmercuric nitrate given intravenously produced acute nephrosis.

Phenylmercuric borate has been used by M. Baer for the treatment of 50 patients with otorhinolaryngological infections who observed no disturbance due to absorption of the compound, or subjective residue. (*Schweiz. med. Wchnschr.* 69: 850, 1939.)

A. Fehr has used phenylmercuric borate as an antiseptic in surgery on 500 patients, and he found that it had a lower toxicity and a higher bacterial action than other preparations with which he compared it. (*Schweiz. med. Wchnschr.* 70: 1221, 1940.)

With regard to the determination of mercury in cases of suspected chronic poisoning, analyses are usually made on the urine, since this is the route of excretion of the metal from the body. A procedure for the determination may be found in "Colorimetric Determination of Traces of Metals" by E. B. Sandell, New York (Interscience Publishers, Inc., 1944) and other similar textbooks.

## TOXIC EFFECTS OF PROCAINE

**To the Editor:**—A girl, aged 19, is hypersensitive to procaine. At age 5, for extraction of a deciduous tooth, a small amount of dental procaine hydrochloride solution (with epinephrine) was injected in the gum, about 1 or 2 minims (0.06 to 0.13 cc.) A few minutes later the child became pale, perspired and was apparently in mild shock. She recovered in a few minutes. At age 12 dental procaine hydrochloride solution was used for nerve block, and in a few minutes the girl was in severe shock, without apparent pulse. Artificial respiration, cardiac stimulants and head down position resulted in recovery. Can anything be done to desensitize this girl, and if increaesd tolerance is developed will it be of long duration?

M.D., Virginia.

Answer.—The symptoms described are not attributable to a procaine allergy. The explanation for the reaction is probably one of the following: (1) a low tolerance for the toxic effects of procaine; (2) a low tolerance for epinephrine, or (3) a psychic effect. The literature does not clarify the status of the activity or toxicity of the procaine in its combination with penicillin. Desensitization to procaine is not an established procedure, and if it were possible the duration of tolerance would probably be short. In this particular instance, since there is no real evidence of an allergy, a desensitization program would definitely not be indicated.

## EFFECT OF STREPTOMYCIN ON THE FETUS

**To the Editor:**—Please evaluate the toxicity of streptomycin on the fetus, when administered to a pregnant woman.

Charles L. Galt Jr., M.D., Carlsbad, N. M.

Answer.—Watson and Stow (The Journal, Aug. 28, 1948, page 1599) observed 2 infants whose mothers had received streptomycin in dosage of 2 Gm. daily for ninety-five and ninety days, respectively, the administration starting in each instance in the second trimester of pregnancy. These infants, observed for nine months and one year, respectively, were normal at birth, developed normally and had normal hearing. Watson and Stow considered that streptomycin might be dangerous if administered during the first trimester of pregnancy, owing to the sensitivity of fetal structures in the anlage stage during that period. Other experiences have not been found.

## TURPENTINES AND DERMATITIS

**To the Editor:**—Recently four house painters have had contact dermatitis which they blame on a "wood turpentine." Is this different from the "gum turpentine" which they used previously?

Shepard G. Aronson, M.D., New York.

Answer.—Until about thirty-five years ago the only turpentine available was "gum spirits turpentine." This substance, which is still produced in large quantities, derives from the distillation of the gum exuded from living pine trees after slashing. This form of turpentine is responsible for some dermatitis, particularly if old, and may induce systemic effects if inhaled or ingested in significant quantities. At about the time mentioned, two new forms of turpentine appeared, the "steam-distilled" and the "destructively distilled" wood turpentines. These different varieties are obtained chiefly from stumps in cutover areas after reduction to chip size. Of these two forms, the "steam distilled" may be the more prolific source of dermatitis, but, undoubtedly, the details of process differ from plant to plant, so that neither sort may be praised or condemned as a generality. Still later, a fourth form of turpentine appeared. This is prepared by extraction of chipped dead pine wood by such solvents as naphtha followed by distillation to recover the naphtha and remove the heavier residues. All of these turpentines have wide and somewhat similar fields of industrial application. All have been associated with the causation of some dermatitis among those exposed.

## DISCOID LUPUS ERYTHEMATOSUS

**To the Editor:**—A 41 year old electric welder has two patches of discoid lupus erythematosus on the bridge of the nose and on the right cheek of nine months' duration. He intends to bring a claim against his employer, assuming that the dermatosis is occupational in origin. He wears a shield when working. Without doubt he is exposed to some ultra-violet radiation from the welding arcs of his fellow workers. In the circumstances outlined can lupus erythematosus be considered a compensable disease?

Walter Weinberger, M.D., Juniata, Pa.

Answer.—Many believe that lupus erythematosus disseminatus of the acute or toxic form may be partially based on hypersensitivity or at least undue exposure to ultraviolet rays. The course of development in some cases suggests this, and in some cases in which the condition eventuated from the discoid variety the patients gave histories of having been sunburned. Nevertheless, in some experiments it was shown that test areas of skin were not more sensitive than the skin of normal controls to ultraviolet rays or other parts of the light spectrum. While there is some suggestive evidence that light may act as a trigger mechanism to the induction of the acute variety, this does not seem to be the cause of the chronic or discoid type. The patient undoubtedly has been exposed to sunlight as well as rays from the welding arc. How are we to allocate the influence from each source if any? The overwhelming majority of experts would say that this man's discoid lupus erythematosus is not a compensable disease.

## CANCER OF CERVIX IN JEWS AND NON-JEWS

**To the Editor:**—Is there any difference in the incidence of carcinoma of the cervix in Jewish and gentile women? Does circumcision of the male influence the production of cervical carcinoma in a manner analogous to its influence in carcinoma of the glans penis? The only conceivable relation would be that a carcinogenic agent is present in the smegma of the uncircumcised male.

M. D., New York.

Answer.—Drs. Treusch, Hunt and Rousuck, in an analysis of 568 consecutive cases of carcinoma of the cervix diagnosed at the Mayo Clinic in the years 1938 to 1942 inclusive (*Am. J. Obst. & Gynec.* 52: 162 [July] 1946), noted that in 566 instances the expressed religious preference of the patient was specifically given as other than Jewish and in not a single instance was the religious preference stated as being Jewish. In 2 instances it was impossible to classify the patients definitely as Jewish or non-Jewish, since the religious preference was given by the patient as none or no preference. However, the authors said that it can be definitely stated that it did not appear at all likely from the other available data that either of these 2 patients was Jewish. They also stated that the estimated Jewish registration at the Mayo Clinic is approximately 7 to 8 per cent and that, according to the "World Almanac" for 1945, about 4 per cent of persons in the United States are Jewish. By using the basis of 7 per cent registration of Jewish patients, they stated that one would have expected to find approximately 40 Jewish women in their series.

According to Dr. Joseph Berkson, Chief of the Department of Biometry and Medical Statistics at the Mayo Clinic, we have no knowledge of the relative incidence of carcinoma of the cervix among Jewish and gentile women as far as the general population is concerned; studies made in selected populations such as medical clinics indicate a smaller incidence in Jewish women, but, in view of the special character of these populations, this conclusion must be looked on with caution, and the possible relation of circumcision in the male to carcinoma of the cervix is not known.

Apparently, there is no available information with respect to the presence of a carcinogenic agent in smegma that is supported by experimental evidence.

## FECAL IMPACTION

*To the Editor:*—Is there a more satisfactory method than manual removal of pasty stools which remain in the rectum of bedfast patients? Oil emulsions by mouth and warm oil or soap enemas seem valueless. Sometimes the finger cannot reach or entirely remove the stool.

M.D., Oregon.

Answer.—The following measures have been found helpful in the removal of fecal impactions and the control of conditions such as that which is described. Warm saline irrigations given every two to three days with the patient in the knee-chest position will suffice in milder cases. The instillation of warm liquid petrolatum, 1 to 3 ounces at a time, at bedtime is helpful. The instillation of a weak peroxide solution helps to break up the fecal mass. This is prepared by adding one part of peroxide to three or four parts of warm water. It should never be stronger than that because of the possibility of a so-called peroxide proctitis. In spite of these measures, it may still be necessary to have the mass broken up manually.

## PARENT BLOOD IN MEASLES MODIFICATION

*To the Editor:*—I have been using human immune serum globulin for modification of measles and have wondered whether it is possible to express its equivalent in cubic centimeters of human blood taken from a middle-aged person who has had measles at some time during childhood. Often for various reasons the use of blood from the respective mother and father will be much more convenient, cheaper and as effective. I use 40 to 60 cc. Is a blood test for syphilis of the donor (a parent) obligatory under the law except where an emergency exists?

R. J. Kent, M.D., Savannah, N. Y.

Answer.—When citrated whole blood drawn from adults who have not recently had measles is used for measles prophylaxis 30 to 60 cc. is thought to have about the same protective value as 2 to 5 cc. of human immune serum globulin. Because the latter is made from pooled lots of serum, its antibody content is more certain than blood from a single donor.

The variables in deciding on the exact dosage are (1) the interval since exposure, (2) the age of the subject being protected and (3) the objective of the procedure, that is, whether complete protection or merely modification of the attack is sought. If the protective substances are given between the fifth and the ninth day after exposure, the majority of subjects will contract modified measles and thus gain permanent immunity. Unless recognizable measles—even though mild—results, a solid immunity cannot be counted on. The passive immunity conferred by the whole blood or immune globulin cannot be relied on to endure longer than a month. Hence the procedure should be repeated if another exposure occurs after this time. A blanket statement regarding the legal requirement for making a blood test for syphilis on parent donors cannot be made because state and local laws vary on this point.

## AMBULANT TREATMENT OF BRUCELLOSIS

*To the Editor:*—1. What is the best way to treat a male patient for Malta fever of about two years' duration? 2. His present complaints are decreasing in severity and the question has been asked as to the percentage of cases that are eventually self limited. 3. Because of the patient's location in Palestine, hospitalization may be impossible. Could you suggest an alternative treatment that could be carried out at home with a minimum of laboratory work?

Morris F. H. Levy, M.D., Brooklyn.

Answer.—The proportion of patients at this stage that might recover satisfactorily without treatment is unpredictable, owing largely to the propensity of the disease to relapse. Since patients can have more or less continuous symptoms for fifteen to twenty-five years, it is advisable to recommend some form of treatment. A simplified form of the treatment recommended and used by Griggs, The Journal, April 3, 1948, page 911, would be as useful as any and less harmful than most, and would not require hospitalization. Any physician skilled in the management of antigen therapy for hay fever should be able to use it successfully.

## KAHN VERIFICATION TEST

*To the Editor:*—The answer to the inquiry on the "Kahn Verification Test" in The Journal, Nov. 6, 1948, page 789, did not contain the basic fact that the verification test was not applicable to the patient in question. As is evident from the enclosed report blank: "The verification test is applicable to cases in which clinical and epidemiologic studies point to false positive reactions." The patient under consideration showed clinical indications of syphilis with a record of seropositivity extending from 1946 to 1948 and with a drop in Kahn units from 20 to 2 or 3 following antisyphilitic therapy.

The verification test was not published as a method for differentiating true and false positive reactions without restriction. If such a method were available, it would replace serodiagnostic tests. The verification test was published (A Serologic Verification Test in the Diagnosis of Latent Syphilis, *Arch. Dermat. & Syph.* **41**: 817, 1940) as a laboratory aid in the establishment of a differential diagnosis between seropositive persons with latent syphilis and persons with false positive reactions in cases in which clinical indications of syphilis do not exist. The value and limitations of the verification test will be discussed in a forthcoming article.

Reuben L. Kahn, Sc.D., Ann Arbor, Mich.

*To the Editor:*—I have read with interest the inquiry of Dr. C. W. Atherton of Fairview, Ill., and the answer printed on page 789 of The Journal, Nov. 6, 1948.

This interchange appears to resurrect again the basic nature of any and all laboratory test routines and findings. While the practicing physician and surgeon yearns for something of laboratory origin which will absolutely provide him with an incontrovertible diagnosis, especially in a case which is confusing, it is a fact that any and all such procedures are but endeavors to contribute additional objective signs in the patient, elicited by special means. The diagnosis in any case is to be made by careful consideration and evaluation of all objective and subjective signs and symptoms of the patient.

It seems to me that such a basic concept has not been sufficiently stressed. He is indeed a wise pathologist who maintains that his function is not to supplant the clinician but to aid him in his determinations by as careful and accurately performed and as well chosen test routines as the problem presented shall justify. Most of the frictions which I have witnessed between laboratory men and clinicians have, in fact, stemmed from the failure of one or the other to recognize the true nature and purport of procedures in clinical pathology and serology.

Whether it be on the positive or the negative side, none of these procedures can be taken as constituting an absolute and final disposition of the diagnostic problem in hand. Two decades ago I published an article on Wassermann-negative syphilis in the *Military Surgeon* (63: 167-181 [Aug.] 1928), in which were quoted the stated opinions of several noted serologists and syphilologists. I do not believe that the basic concept as to the role of laboratory findings has changed one iota in the intervening years.

Albert Hulett, M.D., East Orange, N. J.

## AMPHETAMINE SULFATE PREPARATIONS

*To the Editor:*—In The Journal, February 5, page 422, is a question about amphetamine sulfate and possible harmful doses. You state that toxic symptoms have been noted with as low a dose as 5 mg. and that 15 mg. is the usual maximum dosage.

You might be interested in the case of a young woman who entered our sanatorium not long ago, who had been taking 250 mg. daily or every other day for about two weeks. Not being able to get it on prescription she was buying inhalers, removing the paper impregnated with the drug and steeping it like tea. She was taking it for the "lift" to help her in an anxiety state which was due to a home conflict.

When she came in she was not hallucinating but she was "high." There was an irregular, occasional twitch sometimes of the hands, legs or face. She was perfectly coherent and oriented, but her speech was rather uninhibited. This latter may have been due to a tendency to try to shock members of the family with whom she was not in good rapport. She was definitely euphoric and expansive, laughed freely but only in response to normal situations of humor. She had lost a great deal of weight. There was a slight elevation of the blood pressure, and her reflexes were all highly exaggerated. There were no abnormal reflexes. She gave sixty-three responses in the Rohrschach test; her reaction time was fast. There were practically no sexual responses (her sexual situation is well adjusted), and she found much more than average interest in the colored plates. Many of her responses were highly imaginative, but she could explain her deductions logically. She apparently did not have particular dream patterns of importance, but she stated positively that even before taking the amphetamine she had usually dreamed in technicolor, of brilliant flashes of light and gorgeous buildings in splendid colors. She stated that she had neved used marijuana.

The drug was stopped completely and she almost immediately went into a profound sleep for about forty-eight hours. After four days she was back to average sleep routine. On awaking she was hungry and ate well. Complications of constipation or diarrhea did not occur. When she left, after a ten days' stay, her husband stated that she seemed entirely normal except for weakness due to loss of weight. She did not have desire for the drug at any time that she was with us.

Correspondence with the manufacturer of the inhaler gave us the dosage per unit (250 mg.). The paper impregnated with the drug is plainly marked with a warning about internal use. It is possible that she did not get the full dosage with each one used, but even if she took one every other day she was still getting an enormous dose. Her husband stated that at a minimum she must have used nine in the fortnight previous to her admission.

This experience would tend to show that there must be an enormous difference in individual reaction to amphetamine sulfate and that habituation does not depend on the amount taken as much as on the period over which it is used and the will power of the user to break off the habit.

# THROMBOPENIA AND INCREASED CAPILLARY FRAGILITY IN HEPATIC DISEASE

FRANK B. WHITESELL Jr., M.D.
and
ALBERT M. SNELL, M.D.
Rochester, Minn.

Despite the fact that the hemorrhagic state existing in hepatic disease has been known for several centuries, no entirely satisfactory explanation for it had been advanced until the demonstration of a prothrombin defect in 1935 by Quick and others.[1] While hypoprothrombinemia bears unquestioned responsibility for the hemorrhagic tendency in obstructive jaundice, many students of the subject are unwilling to assign it the sole responsibility for all the instances of bleeding encountered in parenchymal disease of the liver. This has led to an extensive search for other factors associated with hepatic disease which may affect coagulability of the blood. Recently, emphasis has been placed on the demonstration of a circulating anticoagulant, presumed to be heparin. Its place in the hemorrhagic phenomena associated with hepatic disease as yet remains obscure.

It is the purpose of this presentation to emphasize two neglected factors which may be associated with coagulation defects in hepatic disease, namely, thrombopenia and increased capillary fragility. An investigation of the incidence and possible significance of these defects seemed timely and important in view of the many patients currently being seen with the various residua of hepatitis and the apparent increase in the incidence of atrophic cirrhosis.

While most existing textbooks deal with thrombopenia as a chance observation in the terminal phases of hepatic disease, low thrombocyte counts and purpura have been observed in hepatic disease by several previous investigators, including Morlock and Hall,[2] Snell, Vanzant and Judd [3] and others.[4] Snell, Vanzant and Judd [3] in 1930 published one of the earliest accounts recognizing this association. Their case report dealt with a woman aged 29 years in whom a stricture of the common bile duct and obstructive biliary cirrhosis developed subsequent to cholecystectomy. Terminally there was a fall in the number of thrombocytes from 194,000 to 40,000 per cubic millimeter, with a fatal hemorrhagic diathesis. They attributed the final diffuse hemorrhagic phenomena to the combined effects of hypoprothrombinemia and thrombopenia. As will apear in subsequent paragraphs, the present study seems to indicate that diminution of the thrombocyte count and a measurable degree of capillary fragility are commonly found in hepatic disease and are of considerable importance from the point of view of differential diagnosis, prognosis and management.

While increased capillary fragility and thrombopenia frequently coexist clinically, they are, as the data to be presented will indicate, independent phenomena in many cases of cirrhosis and hepatitis. Often a common causative agent may depress thrombocyte production and simultaneously damage capillary endothelium, but abnormal fragility and thrombopenia are not necessarily synchronous in occurrence. It is possible that thrombocytes may normally play an important role in maintaining the integrity of the capillary wall by sealing defects in the capillary wall against the escape of erythrocytes. The work of Bedson,[5] however, suggests that thrombopenia or even complete absence of thrombocytes is not capable alone of producing purpura. It is a common clinical experience to find high indexes of capillary fragility in the presence of repeatedly normal thrombocyte counts, as well as normal capillary fragility with decided thrombocyte depression.

Capillary fragility depends on the cohesive resistance of the cells of the capillary wall and the intercellular cement substance to those factors tending to disrupt the integrity of the vessel wall. Reduction in thrombocytes alone will not induce increased fragility. Injury to the capillary wall must exist and in itself may be sufficient, without thrombopenia, to increase fragility. There appears to be little agreement in the literature, however, as to the exact site of such injury. In some instances, notably the toxemias and septicemias, it has been assumed that direct injury to the endothelial cells occurs. Chambers and Zweifach,[6] on the other hand, have suggested that injury to the cement substance surfacing the capillary lumen or inadequate production of it may be the important derangement predisposing to capillary hemorrhage. The work of Peck, Rosenthal and Erf [7] has implicated the supporting tissues about the capillaries, particularly the elastic fibers. Meyer

and Chaffee[8] have linked these changes to the action of hyaluronidase on these supporting tissues, believed to be rich in hyaluronic acid. With liquefaction of the sustaining tissues, intravascular pressure first dilates and then ruptures the vessels.

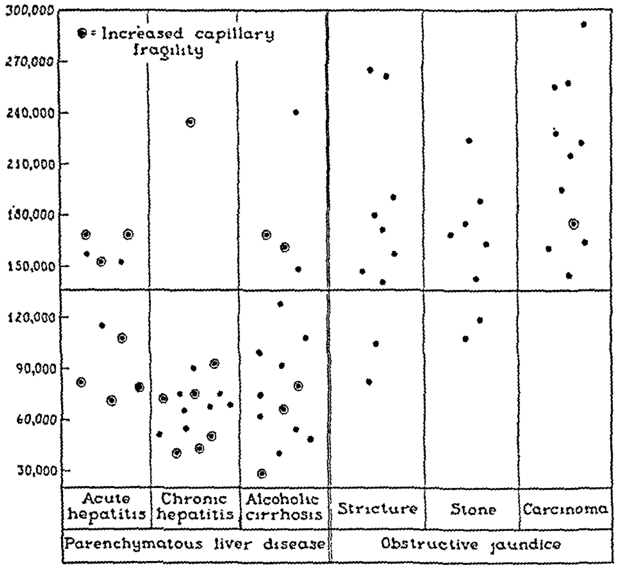

Fig. 1.—Mean thrombocyte counts in hepatic disease. The vertical column of figures at the left shows the mean thrombocyte count.

All of the many tests devised to measure capillary resistance depend on the production of petechiae by a process of rupture of the capillary wall. Two of these methods are familiar to all physicians: the Rumpel-Leede test and the negative pressure test of Hecht. In 1937, Peck, Rosenthal and Erf[9] reported a third method, in which the intradermal injection of snake venom is employed. In the present study we employed the simplest of these procedures, the Rumpel-Leede technic. An ordinary blood pressure cuff placed about the arm was inflated to 100 mm. of mercury pressure and then left in place for exactly five minutes. On release of the pressure the number of petechiae was counted in a circular area exactly 1 inch (2.5 cm.) in diameter. This determination was made on both arms, and the petechial index was calculated from the mean value obtained.

### PRESENT STUDY

In our study we followed the practice of determining the thrombocyte level by direct counting immediately after diluting the blood samples with a 2 per cent solution of sodium citrate in isotonic sodium chloride solution. Each sample was doubly checked, and, to minimize error, dependence was placed on multiple counts made on successive days instead of on single determinations. In each instance, at least three such counts were made, and the count finally considered representative of any particular case was accepted to be the mean of these multiple counts.

To establish standards of normal, fragility was determined and thrombocyte counts were made on a control series of 20 patients who represented routine hospital admissions for complaints other than those due to hepatic disease or a blood dyscrasia. Many were patients with a peptic ulcer, with and without bleeding, and all failed to manifest any retention of dye on routine testing of hepatic function with sulfobromophthalein sodium (bromsulfalein). In this way, with the technic described, the normal petechial index of capillary fragility was found to lie between 0 and 23, with most patients exhibiting less than 6 petechiae. Thrombocyte counts in these same patients established a range of normal from a low of 137,000 to a high of 219,000. We therefore accepted as our normal levels any petechial index of less than 23 and any mean thrombocyte count that was more than 137,000. The laboratory work was performed in the Division of Clinical Laboratories and in the Division of Biochemistry.

The cases in which clinical data for this investigation have been gathered represent consecutive hospital admissions for hepatic disease of one type or another over a period of five months. In this way, any bias inherent in selection of cases has been fairly well excluded. Distribution of these cases according to the type of lesion, with the respective thrombocyte counts, is shown in figure 1. Seventy cases in all were included in the study. Twenty-nine of these were classified as cases of extrahepatic obstructive jaundice. These 29 cases included 8 cases of stone in the common duct, 10 cases of stricture of the common duct and 11 cases of malignant obstruction, by carcinoma of either the bile ducts or the head of the pancreas. In 4 of these cases only thrombopenia was exhibited, and in only 1 patient was an increase in capillary fragility dent. In the remaining 41 cases in our series ther definite parenchymal disease of the liver in of hepatitis or cirrhosis. In all but 4 of th there was thrombopenia or increased ca or both. It is mainly from this

[8] Meyer, K., and Chaffee, E.: The Mucopolysaccharides of Skin, J. Biol. Chem. **138**: 491-499 (April) 1941.

[9] Peck, S. M.; Rosenthal, N., and Erf, L. A.: Intradermal Venom Reaction: A New Method of Determining Capillary Fragility, Proc. Soc. Exper. Biol. & Med. **35**: 614-616 (Jan.) 1937.

parenchymal disease was manifested that subsequent data have been gathered. Those cases in other categories have been included chiefly for comparison.

Ages of the patients with thrombopenia ranged from 9½ to 70 years, with male patients predominating by a ratio of 2.2 : 1. In 2 patients a diagnosis of homologous serum jaundice was established. In many of the cases of chronic hepatitis it was difficult to arrive at any definite idea as to time of onset or duration of the disease. Biopsy of the liver in these cases often revealed evidence of a long-standing progressive pathologic process. All of the patients with acute hepatitis were decidedly icteric and had high elevation of the value for serum bilirubin; most of the patients with chronic hepatitis manifested minimal clinical icterus and only slightly elevated values for serum bilirubin. As would be expected, most patients with alcoholic cirrhosis exhibited little or no jaundice. In none of these categories did there appear to be any correlation between the presence or the degree of jaundice and the thrombocyte count or the petechial index of fragility.

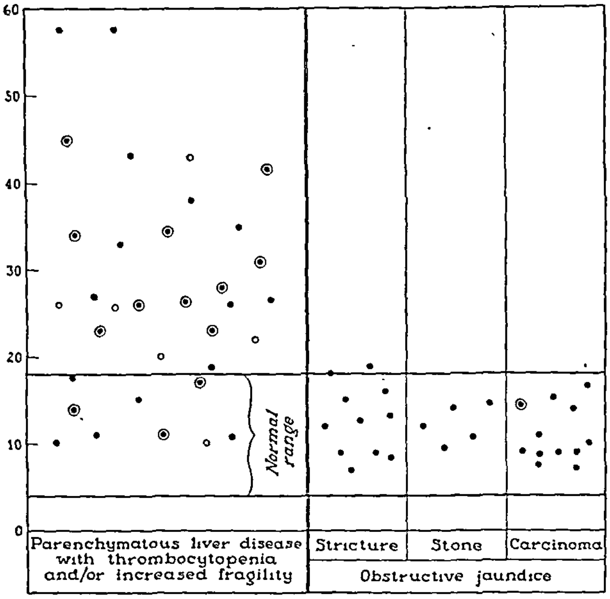

Fig. 3.—Relationship of thrombopenia and increased capillary fragility to the values of serum gamma globulin. The vertical column of figures at the left indicates the zinc sulfate (Kunke) turbidity estimation of gamma globulin in units. The black dot indicates thrombopenia; the circle indicates increased capillary fragility, and the circle-enclosed dot indicates thrombopenia and increased capillary fragility.

One of the symptoms most commonly mentioned by these patients was an increased tendency to bleed with a history of recurrent epistaxis, bleeding gums and melena, at times extending back over several years. This observation appeared as a rule to be related to severe parenchymal damage to the liver. Since many of these patients manifested varying degrees of prothrombin deficiency in addition to their thrombocyte and capillary defects, it is difficult to evaluate the exact role of each abnormality in this tendency toward increased bleeding.

While the irreversibility of the hypoprothrombinemia [illegible]uently appeared to supersede the thrombocyte defi- [illegible] as an explanation for bleeding, no correlation [illegible] between the presence or degree of thrombo- [illegible]creased capillary fragility and the pro- [illegible] Low thrombocyte counts frequently [illegible]ods without demonstrable bleeding and, conversely, often appeared to have been responsible for a fatal hemorrhagic state when the prothrombin time was at or near normal limits. This was particularly so when the blood thrombocyte counts were depressed to a critical level of 50,000 or below. In several surgical patients bleeding on this same basis proved serious and extremely difficult to control, necessitating transfusions and extensive local use of thromboplastic substances.

On physical examination of these patients with thrombopenia and increased capillary fragility, palpably enlarged spleens were found in 30 per cent of the cases of acute hepatitis, in 43 per cent of the cases of chronic hepatitis and in 29 per cent of the cases of alcoholic cirrhosis. The liver was palpably enlarged in 70 per cent of the cases of acute hepatitis, in 43 per cent of the cases of chronic hepatitis and in 71 per cent of the cases of alcoholic cirrhosis. Ascites was found in only 20 per cent of the cases of acute hepatitis, in 43 per cent of the cases of chronic hepatitis and in 57 per cent of the cases of alcoholic cirrhosis.

Since stress has been placed on the association of thrombopenia, increased capillary fragility and parenchymal disease of the liver, it is important to review this relationship in terms of the physiologic and biochemical alterations ordinarily encountered in hepatocellular disease. The prothrombin time and values for serum bilirubin have already been discussed.

*Plasma Proteins.*—While it is commonly stated that the concentration of total protein is reduced in parenchymal disease of the liver, in many of our cases the totals were in the normal range. Invariably, however, when values in the normal range were obtained, they were due to an increase in the globulin fraction to a value well above the usually accepted normal of 2.7 Gm. per hundred cubic centimeters, with either equalization or reversal of the albumin-globulin ratio (fig. 2). This is in agreement with the observations of others, including the recent report of Salvesen and Lödöen.[10]

*Additional Laboratory Data on Cases Reported*

| Procedure | Normal Values | Case Number 1 | 2 | 3 | 4 |
|---|---|---|---|---|---|
| Thrombocytes per cubic millimeter (mean) | More than 137,000 | 67,000 | 43,000 | 75,000 | 49,000 |
| Prothrombin time, seconds | 19 to 20 | 23 | 21 | 25 | 24 |
| Serum bilirubin, mg. per 100 cc. | | | | | |
| Direct | 0 | 1.2 | 1.6 | 0 | 3.4 |
| Indirect | Less than 0.6 | 0.7 | 1.4 | 1.4 | 0.8 |
| Serum proteins, Gm. per 100 cc. | 6.8 | 7.6 | 7.6 | 6.6 | 6.1 |
| Albumin | 4.1 | 2.7 | 3.2 | 3.5 | 3.0 |
| Globulin | 2.7 | 4.9 | 4.4 | 3.1 | 3.1 |
| Zinc sulfate turbidity, units | 4 to 18 | 58.2 | 45 | 26 | 11 |
| Thymol turbidity, units | 5 | 22 | 24 | 3.5 | 4 |
| Cephalin-cholesterol flocculation, grade | 0 | 4 | 4 | ... | 4 |
| Blood cholesterol, mg. per 100 cc. | 150 to 250 | 155 | 167 | 155 | 160 |
| Blood cholesterol esters, mg. per 100 cc. | 100 to 175 | 62 | 78 | 105 | 56 |
| Alkaline phosphatase, Bodansky units | 5 | ... | 4.5 | ... | ... |
| Sulfobromophthalein sodium retention, grade | 0 | 2 | 3 | ... | 4 |

9. Brain, [illegible] Neuropsychiatry;

10. Roger, H.; [illegible] -otiques aigues lum[illegible] -e, Rev. neurol. [illegible]

[10] Salvesen, H. A., and Lödöen, O.: Variations in the Serum Proteins in Liver Disease with Special Reference to Their Diagnostic Significance, Acta. med. Scandinav. **130:** 525-558, 1948.

Changes in the globulin fraction were studied further by investigation of the gamma globulin in the serum, employing the zinc sulfate turbidity method of Kunkel.[11] In most instances definitely elevated values were found (fig. 3). We do not feel, however, that the globulin exerts any direct influence in reducing the thrombocyte count. Ten cases of multiple myeloma, in all of which pronounced hyperglobulinemia occurred, were reviewed, and in all the thrombocyte levels were normal. In addition, the in vitro effect of relatively large amounts of gamma globulin on the thrombocyte count was checked and no change was observed. In all probability the thrombocyte defect in parenchymal disease of the liver occurs concomitant with but not secondary to the hyperglobulinemia encountered.

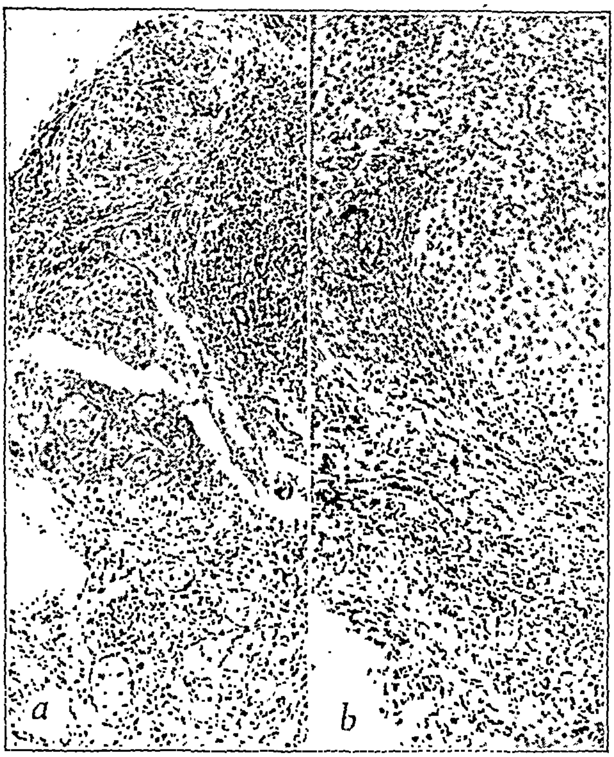

Fig. 4.—Appearance of the hepatic tissue stained with hematoxylin and eosin; *a*, case 1 (× 90), and *b*, case 2 (× 100).

*Sulfobromophthalein Sodium Test.*—This test is generally conceded to be a sensitive indicator of hepatic disease in the absence of jaundice. All of our patients without icterus but with thrombopenia or increased capillary fragility manifested dye retention of more than 12 per cent at the end of one hour.

*Flocculation Tests of Hepatic Function.*—With the close correlation between thrombopenia and increased capillary fragility and the plasma colloids, it was not surprising to find a similar correlation with the flocculation tests of hepatic function. In 88 per cent of our patients cephalin-cholesterol flocculation tests gave strongly positive results, and in 64 per cent thymol turbidity was increased.

*Alterations in Other Blood Factors.*—To ascertain whether or not the thrombocyte defect in parenchymal disease of the liver represented a specific involvement of a single cell line or was merely part of a generalized depression of all of the formed elements of the blood, simultaneous erythrocyte and leukocyte counts were made and differential smears were examined for all of our patients. With the exception of a mild secondary anemia in about one third of these patients, no other change was noted. These observations on the peripheral blood were substantiated by studies of sternal marrow on a number of our patients with thrombopenia. All revealed not only active marrows but also megakaryocytes in adequate numbers.

It was difficult to secure a true appraisal of the bleeding, coagulation and clot retraction times because of the associated hypoprothrombinemia in most cases. In general, however, the bleeding time was prolonged with normal or slightly prolonged clotting time and poor retractility of the clot.

We can best present the pathologic changes encountered in these patients with thrombopenia and increased capillary fragility by briefly reviewing several typical cases of chronic hepatic disease in which the results of biopsy of the liver were available. It will be seen that a variety of pathologic pictures may be associated with thrombopenia.

## REPORT OF CASES

Case 1.—A girl aged 17 years was admitted to the hospital with a history of recurrent epistaxis and bleeding gums for the past two years; these symptoms had been more pronounced during the last six months before her visit to the clinic. Her past history was essentially normal except for an extensive series of orthopedic surgical procedures done three years before for severe scoliosis.

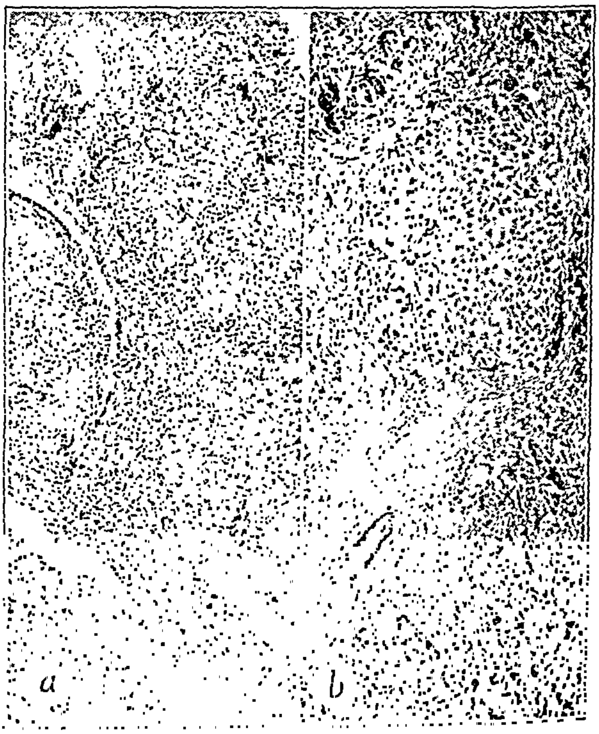

Fig. 5.—Appearance of the hepatic tissue stained with hematoxylin and eosin; *a*, case 3 (× 50), and *b*, case 4 (× 100).

On physical examination she appeared slightly icteric; t'
was a small subconjunctival hemorrhage on the left and :
oozing of blood from the margins of the gums; sthesia,
was palpable 2 fingerbreadths below the costal
her spleen also was palpable. omplications

11. Kunke f Alterations of Serum Gamma Globulin by a Proc. Soc. Exper. Biol. & Med. **66**: 217-224 .

The results of a sternal marrow study were not diagnostic. There was some increase in eosinophils, but the megakaryocytes seemed normal in number.

A biopsy of the liver performed with the aid of a Vim-Silverman needle showed that the architecture of the liver was barely discernible; fibroblastic, cellular infiltration of the hepatic lobules was so pronounced that it split the individual lobules into small, acinar-like groups of hepatic cells. No regeneration of bile ducts was evident, and no deposits of bilirubin could be seen; some of the hepatic cells had undergone eosinophilic degeneration (fig. 4*a*). This was believed to represent severe subacute hepatitis.

CASE 2.—A white man aged 59 years was admitted to the hospital with the complaint of painless jaundice, malaise and anorexia of ten days' duration. There was a past history of two similar episodes; one had occurred eight years previously and had lasted for three to four months, and the other had occurred seven months previously, had lasted for six weeks and had required hospitalization.

On physical examination moderate icterus was evident and the liver could be felt 2 fingerbreadths below the umbilicus; it was firm, smooth and not tender. The spleen was not palpable. There was a pronounced increase in capillary fragility.

The mean thrombocyte count was 43,000. The results of hepatic function studies are given in the table.

A needle biopsy of the liver revealed severe distortion of the hepatic architecture with extensive fibrosis (fig. 4*b*). A very cellular fibrous tissue replaced much of each lobule, and in some areas just a few parenchymal cells could be seen, isolated by fibrous tissue. Regeneration of parenchymal cells and bile ducts was minimal. Some intracellular deposits of bilirubin could be seen scattered throughout the section. This was considered to be the picture of a degenerative cirrhosis or chronic atrophy of the liver.

CASE 3.—A boy aged 14 years was admitted to the hospital for diagnosis because of weakness, malaise, unexplained fever and epistaxis. Three years previously he had had a similar episode lasting six weeks, and at that time his physician in his home community had noted "an enlarged liver and spleen." One year before admission he had a four day episode of nausea, vomiting, fever and pain in the upper part of the abdomen with hepatomegaly and splenomegaly. All symptoms subsided except the fever; the temperature continued to rise to 100 or 101 F. each afternoon. His family history was significant in that a brother aged 14 years had died "with cirrhosis" eight months after splenectomy, which was several months before the onset of this patient's illness.

On physical examination no icterus was evident. The liver was enlarged to 2 fingerbreadths below the costal margin, and it was soft and not tender. The spleen was palpable 5 cm. below the costal margin. No spiders or ascites were evident.

The mean thrombocyte count was 75,000. The results of hepatic function studies are given in the table.

A needle biopsy of the liver disclosed that the architecture of the liver was fairly well preserved, but considerable destruction could be seen at the periphery of the lobules (fig. 5*a*). The portal spaces were filled with an active inflammatory tissue which contained polymorphonuclear cells, round cells and fibroblasts. Many young regenerating bile ducts could be seen. This was believed to be consistent with the chronic phase of a viral hepatitis and possibly the beginning of postnecrotic cirrhosis.

CASE 4.—A white man aged 40 years was admitted to the hospital with a history of excessive alcoholism of fifteen years' duration. Six months before admission he had noted the onset of case of fatigability, anorexia, mild icterus, ascites and eripheral edema. He was admitted to the hospital in shock, tly after several severe episodes of hematemesis and sp

adm ysical examination mild icterus was evident and the lpably enlarged to the level of the umbilicus. The t be felt. There was pronounced ascites and l edema. No spider angiomas or palmar

The mean thrombocyte count was 62,000, and an increased capillary fragility was evident. The results of hepatic function studies are given in the table.

Needle biopsy of the liver disclosed that the dominant feature was pronounced fibrosis, with regeneration of bile ducts throughout the section (fig. 5*b*). Only minimal nodular regeneration was evident, and little or no fat or bilirubin was seen. This was considered to represent typical portal cirrhosis of long standing.

## COMMENT

The primary significance attached to the observation of a tendency to bleed, thrombopenia and increased capillary fragility in hepatic disease unquestionably resides in the importance of this syndrome in differential diagnosis. Often this entity may so closely simulate the accepted clinical picture of essential thrombopenic purpura as to deceive not only the internist but the trained hematologist as well. When confirmatory signs of hepatic disease such as ascites, hepatomegaly and edema are present, there is but slight hazard of confusing these two entities. Unfortunately, however, as we have noted, these signs frequently are not evident, so that it is extremely important for the clinician to maintain a high index of suspicion toward any diagnosis of idiopathic thrombopenic purpura until thrombopenia secondary to disease of the liver has been excluded. We cannot emphasize too strongly the imperative need for a careful evaluation of hepatic function in all patients with so-called idiopathic thrombopenic purpura. If necessary, punch biopsy of the liver should be performed, since this procedure may be carried out with negligible risk and will often yield conclusive proof as to the diagnosis. It is only by a careful process of exclusion that secondary thrombopenia of hepatic causation can be ruled out.

While these conclusions pertain to differential diagnosis, the thrombopenia of hepatic disease has equally important surgical connotations. This is particularly so today with the increasing tendency toward surgical attack on the complications of cirrhosis by such measures as lienorenal shunt. It is also significant when surgical procedures are contemplated on the bile ducts for the relief of prolonged obstruction which has already produced serious secondary parenchymal damage in the form of biliary cirrhosis. Our observations in these circumstances, as we have shown, are at variance with the observations of Coller and Farris[12] in 1941, who stated, "It is generally agreed that the blood of jaundiced patients is not deficient in calcium, fibrinogen or platelets." To the contrary, we feel that a decided reduction in number of thrombocytes may exist, and if these patients are subjected to operation, the thromboplastic deficit may add materially to the risk of serious hemorrhage. It must be emphasized that in these circumstances estimations of the prothrombin time alone are not sufficient to secure an adequate evaluation of the hemostatic capabilities of the patient.

Concomitant with the added risk of hemorrhage there is also the distinct danger of one's precipitating terminal hepatic insufficiency in these patients by adding to the functional burden of a liver with a reduced reserve.

## CONCLUSIONS

1. Thrombocyte and capillary defects are extremely common in parenchymal disease of the liver.

2. There is some general correlation between the occurrence of these defects and an abnormal state of the

serum colloids, such as, notably, a great increase in gamma globulin.

3. It is important to differentiate the thrombocytic and capillary defects due to hepatic disease from true idiopathic thrombopenia. All patients with iodiopathic thrombopenic purpura should be subjected to a complete evaluation of hepatic function, supplemented by biopsy of the liver if necessary, before splenectomy is considered.

4. When thrombopenia and increased capillary fragility secondary to hepatic disease occur, surgical treatment is complicated by the added risk of hemorrhage over and above that due to any existing deficiency of prothrombin. In addition, there is the danger of precipitation of terminal hepatic insufficiency.

# THE DANGERS OF INTRATHECAL MEDICATION

GEORGE WILSON, M.D.
CHARLES RUPP, M.D.
and
WILLIAM W. WILSON, M.D.
Philadelphia

The intrathecal space is so frequently chosen for the administration of serums, drugs, antibiotics and anesthetic agents that it is sometimes forgotten that numerous serious and tragic sequelae have been reported following the use of this route. It therefore seems advisable to reemphasize the dangers which may ensue and critically to reevaluate the rationale of this mode of drug administration.

The injection of any foreign substance into the subarachnoid space produces an aseptic meningeal reaction characterized principally by pleocytosis and increased protein content.[1] This reaction may occur following a purely diagnostic spinal puncture, a later tap revealing pleocytosis. Reynolds and Wilson[2] reported 3 cases in which headache, nuchal stiffness, stupor, delirium and fever appeared from six to twelve hours after lumbar puncture. Repeated taps revealed sterile cloudy fluid with cell counts ranging from 2,900 to 17,670.

The introduction of each new therapeutic agent into the intrathecal space has been inevitably followed by reports of serious damage to the nervous system. Usually, neurologic complications occur more frequently when the neural tissue is already damaged. The Swift-Ellis treatment resulted in many cases of paraplegia, vesical disturbances and death from concomitant meningitis.[3] The severe neurologic catastrophes of this method of therapy were undoubtedly an important factor leading to its almost universal abandonment. Purulent aseptic meningitis was noted in 10 cases of tetanus, treated with antiserum intraspinally, which came to autopsy at the Laboratory of Neuropathology of the Philadelphia General Hospital during a three year period.[4] Likewise, grave neurologic sequelae occurred following the intrathecal use of antimeningococcic serums and convalescent serums for poliomyelitis.

## NEUROLOGIC SEQUELAE OF SPINAL ANESTHESIA

Neurologic disturbances following intrathecal medication, even when the nervous system is presumably free from disease, are illustrated by the complications following the injection of alcohol and spinal anesthetics. A Brown-Séquard paralysis following paravertebral alcohol injection for angina pectoris has been reported by Molitch and Wilson.[5] Other neurologic residuals, subsequent to intraspinal injection of alcohol, are not uncommon.

A white housewife, aged 24, was given a subarachnoid injection of 16 cc. of absolute alcohol between the fourth and fifth thoracic vertebrae to control severe asthma. There immediately developed a transverse myelitis with complete paraplegia, disturbance of sphincter control and sensory loss below the third thoracic vertebra. Three years later the patient remained unimproved.

Neurologic complications following spinal anesthesia have been reported by many authors. In Thorsen's[6] series of 2,493 cases, aseptic meningitis occurred once in every 800 instances of spinal anesthesia and symptoms pointing to injury of the medullary substance, nerve roots or cauda equina occurred at least once in every 200 cases. Such injuries may arise from neurotoxic and myelolytic effects of the anesthetic agent producing aseptic meningitis or an obliterative arachnoiditis. Lesions of the cauda equina or conus medullaris, neuritis, radiculitis, meningomyelitis, transverse myelitis, myeloradiculitis, focal cerebral lesions, cranial nerve paralyses, aseptic and septic meningitis and arachnoiditis have been reported.[7] The symptoms appeared within a few hours to several weeks after the anesthesia.[8] Why severe neurologic complications should result in some instances while many patients are free of after-effects is not clear. It is usually accepted that a history of some previous disease or injury involving the nervous system, particularly the spinal cord, is a definite contraindication to the use of spinal anesthesia. The dangers of spinal anesthesia in such instances are illustrated by the following case:

A white housewife aged 44 had had infantile paralysis at the age of 2 years, from which she recovered with no disability except deformity and weakness of the left foot. Three weeks after the patient submitted to spinal anesthesia for an appendectomy there developed progressive weakness and incoordination of the lower extremities and urinary urgency; she was unable to sit erect, stand or walk. Examination revealed spastic paraplegia with partial sensory loss below the fourth thoracic vertebra. Spinal fluid examination and roentgenograms of the spine revealed no abnormalities. There has been no improvement over a five year period. Subsequently the patient received a substantial financial award in settlement.

Spinal anesthetics may also precipitate the appearance of symptoms and signs of some neurologic disorder previously latent.

A white man aged 28, a crane operator, received spinal anesthesia for an operation for removal of a ruptured cartilage from the right knee. A few days later there developed urinary incontinence and weakness of the right leg. Later the man complained of pains in the lower part of the back, paresthesias and weakness of both hands. His symptoms have waxed and waned during the past three years. Examination now shows

bitemporal optic pallor, a spastic ataxic gait, pronounced weakness of both legs, slight weakness of both arms, increased deep reflexes, absent abdominal reflexes, bilateral pathologic great toe and digital reflexes and some disturbance in position and vibratory sense in the legs. The patient is considered to be suffering with multiple sclerosis.

A Negro aged 28, complaining of pain in the right upper abdominal quadrant, without any reported neurologic signs, received spinal anesthesia for a laparotomy which revealed a normal gallbladder. Thereafter he complained of pain in the lower thoracic area, weakness and numbness of the legs and urinary incontinence. There rapidly developed signs of a complete transverse lesion at the level of the eighth thoracic vertebra. Spinal fluid and roentgenographic examinations gave results that were within normal limits. Necropsy disclosed an intramedullary tuberculoma in the midthoracic area.

Spinal anesthesia is contraindicated also in patients with congenital anomalies of the nervous system, with known virus infections and with a history of delayed return of motor function or severe paresthesias following a previous spinal anesthesia. Conditions resulting in severe inanition and likely to be accompanied with well defined vitamin deficiency are also probably contraindicative, even though clinical neurologic symptoms are not present prior to administration of the anesthetic.

A farmer aged 55 had symptoms of peptic ulcer for seven years, during which interval he cooperated poorly with medical treatment. For three months previous to operative intervention he had vomited frequently. His dietary intake had been limited chiefly to milk and cream, and he had lost 50 pounds (22.7 Kg.). Spinal anesthesia was employed for a gastric resection. Three days after the operation the patient complained of urinary incontinence and severe paresthesias of the legs. Neurologic examination disclosed evidence of a peripheral neuropathy with deep muscle tenderness, bilateral foot drop, absent ankle jerks and a stocking type of anesthesia. The patient was placed on a regimen of large doses of thiamine hydrochloride given by the intramuscular route. The paresthesias subsided in the course of a month, but the motor weakness spread to involve both lower extremities, and a complete loss of sensation developed below the first lumbar vertebra. Six months later examination of the spinal fluid revealed a block, which was shown by roentgenologic studies employing a contrast medium (pantopaque®) to be in the lower thoracic area. Laminectomy disclosed a dense inoperative adhesive arachnoiditis. There has been no improvement in the neurologic condition of the patient in three years.

## THERAPEUTIC SPINAL FLUID CONCENTRATIONS

In recent years the proved value of the sulfonamide drugs, penicillin and streptomycin in the treatment of meningitis and other infections of the nervous system has led to their frequent intrathecal administration. It was early demonstrated that adequate therapeutic concentration of sulfonamide compounds could be obtained in the spinal fluid following the oral or parenteral administration of these agents. Nevertheless, intrathecal administration was resorted to by some, despite the fact that most of the sulfonamide drugs were known to be neurotoxic. Many cases of peripheral and local neuropathy, encephalomyelitis, toxic psychosis and hemorrhagic encephalitis occurred following systemic administration of the drugs.[9] Paraplegia, cauda equina paralysis, radiculitis, arachnoiditis and necrosis of the spinal cord were reported following subarachnoid administration. Roger and his co-workers,[10] reporting 3 cases of necrosis of the cord, recommended that the intraspinal route be definitely abandoned.

In the early days of penicillin therapy, when the supply was limited, intrathecal injection was considered mandatory because it was thought that insufficient spinal fluid concentrations were obtained following systemic administration of the agent. The evidence whether adequate therapeutic concentrations of penicillin can be obtained in the spinal fluid following systemic administration has been contradictory. Rosenberg and Sylvester[11] obtained satisfactory spinal fluid concentrations in 8 cases of meningitis following intravenous or intramuscular injections of 20,000 to 40,000 units of penicillin. Dumoff-Stanley and her co-workers[12] concluded that systemic administration of penicillin in the commonly used dosages will not consistently produce adequate therapeutic concentrations in the spinal fluid. Extremely high dosages with high serum levels must be used before therapeutic concentrations can be detected even inconsistently. Recently Boger, Wilson and Baker[13] have shown that in neurosyphilitic patients without evidence of meningeal irritation therapeutic levels of penicillin in the spinal fluid could be obtained when 100,000 units of the drug were given intramuscularly at three hour intervals. When, in addition, carinamide was given orally every three hours, the spinal fluid concentrations were increased fourfold. Penicillin (500,000 units) and carinamide (3 Gm.) given together intravenously produced therapeutic spinal fluid concentrations in one hour.

## NEUROTOXIC ACTION OF PENICILLIN

The neurotoxic action of penicillin has been investigated by Johnson, Walker and their associates.[14] Large doses of penicillin injected intrathecally in some instances produced convulsions followed by coma or death. In a series of 51 patients with conditions other than primary disease of the central nervous system, the electroencephalogram was found to be abnormal in more than 60 per cent even when penicillin was administered only systemically. Johnson and Walker[15] also report a case in which 50,000 units of intraventricular penicillin produced coma and vascular collapse. Fifteen thousand units of the drug produced transient twitchings of one side of the body lasting four hours. Clinical reports of neural damage following intrathecal administration of penicillin soon appeared. A subarachnoid block was noted in 6 of 67 cases reported by Appelbaum and Nelson.[16] In Sweet's[17] series of 16 patients with pneumococcic meningitis, pain developed in the legs and lower part of the back of 2 after intrathecal injection. These symptoms disappeared after penicillin therapy was discontinued. Two patients manifested severe reactions with sharp pains in the legs, dysesthesia, vesical disturbances and paralysis of both legs. There was a gradual recovery after the drug was discontinued.

One patient who received penicillin both intracisternally and by the lumbar route died after the spinal fluid became bloody. Transverse myelopathy which occurred in a woman aged 66 was reported by Siegal.[18] Practically no improvement had occurred four months later. Erickson, Masten and Suckle,[19] reporting 4 cases, stated that the most frequent and characteristic reaction occurred in the meninges and led to adhesive spinal arachnoiditis and in severer cases to transverse myelopathy. The frequency of relapses in cases of meningitis treated with penicillin suggested the possibility that a reactive exudate, resulting from the irritating effects of penicillin in the subarachnoid space, may encyst areas of infection in the meninges which are inaccessible to penicillin by any route and these may later lead to reinfection. In another paper Walker,[20] reports the development in a patient of difficulty in urination, constipation and pain above the left ankle following intrathecal injection of the drug. Examination showed perianal hyperesthesia, an atonic rectal sphincter, sluggish ankle jerks and weakness on flexion of both knees and the left foot. The symptoms were still present five months later. In another patient transverse myelopathy developed following intrathecal administration of 75,000 units of penicillin. Chronic leptomeningeal thickening was apparent when laminectomy was performed.

We have personally observed a number of instances in which transient vesical disturbances, paresthesias and moderate weakness of the lower extremities with diminished or absent knee jerks and ankle jerks followed the intrathecal administration of penicillin. All symptoms gradually cleared. The following case illustrates a severer complication.

A girl aged 4 months contracted lobar pneumonia. The pediatrician thought nuchal rigidity was present on clinical examination, but results of the spinal fluid examination were normal. Nevertheless 10,000 units of penicillin were given intrathecally on two occasions. Recovery was considered uneventful until two weeks later, when it was noticed that the infant did not move her legs. Examination revealed a spastic paraplegia with a sensory loss below the level of the first lumbar vertebra. Laminectomy disclosed extensive adhesive arachnoiditis.

### TOXICITY OF STREPTOMYCIN

Since early reports indicated that relatively little streptomycin diffused into the spinal fluid following intramuscular injection, although larger amounts might be found in the presence of meningitis, supplemental intrathecal administration of the drug was recommended. Evidence of the toxic effects of intrathecal streptomycin is rapidly accumulating. Meningeal signs and pleocytosis of the spinal fluid were observed by Farrington and co-workers.[21] Patients receiving larger doses of streptomycin intrathecally had headaches, nystagmus, bradypnea, urinary retention and somnolence that at times approached stupor. Similar complications were noted by other investigators. Cairns[22] and his colleagues reported that subsequent to the intrathecal injection of streptomycin 4 patients became comatose and 2 died of respiratory failure. They cautioned that intrathecal use of the agent was dangerous. Applied to the cerebral cortex of cats and monkeys in doses of 1,250 units, streptomycin induced convulsions; cisternal injection of 5,000 units in a monkey produced transient signs of severe cerebellar disease. We have seen several patients in whom pronounced cerebellar signs appeared immediately after streptomycin was given intracisternally.

In 4 patients who died from tuberculous meningitis after unsuccessful intrathecal and intramuscular administration of streptomycin, the spinal meninges have exhibited a considerably more extensive purulent exudate and a much more thinned-out spinal cord than is found in untreated patients. It is uncertain whether these changes are attributable to the use of streptomycin or whether prolongation of life has permitted a more intensive development of the tuberculous process.[4]

### COMMENT

There is no doubt that intrathecal injections of drugs, anesthetics and antibiotics produce neurologic complications in many cases. The neurologic residuals are often serious, permanent, disabling and unamenable to any known therapy. Their prevention is of prime importance. Consideration must be given to whether intrathecal administration is necessary and, if it is, whether the benefits derived therefrom outweigh the potential hazards. In reference to spinal anesthesia, Kennedy[8] has stated that "the gravity of possible spinal arachnoiditis and subsequent paralysis must enter into the meditations of surgeons and anesthetists when determining procedure." Certainly an adequate neurologic history and examination should be completed for every patient considered for spinal anesthesia, and another anesthetic should be chosen if any abnormalities are observed or a history of previous neurologic disorder is elicited.

When adequate spinal fluid concentrations of an agent can be obtained following systemic administration, as with the sulfonamide compounds and penicillin, intrathecal administration is truly meddlesome mischief and is strictly contraindicated. In respect to the intrathecal use of streptomycin, more extensive studies are indicated to confirm definitely whether adequate therapeutic spinal fluid concentrations are obtained from systemic administration alone. A controlled study in which alternate patients did not receive intrathecal medication would be of interest. One should remember that the hematoencephalic barrier is diminished in disease of the nervous system, and adequate diffusion may occur under pathologic conditions even though permeability is inadequate in normal experimental subjects. Likewise, as stressed by Reese and Masten,[23] the spinal fluid reflects only what is going on in the adjacent neural tissues. The infection is in the meninges and neural parenchyma, which have an adequate blood supply. Diffusion of therapeutic substances through the subarachnoid space is slow, and many regions of the nervous system are relatively inaccessible. Since the usual direction of flow of cerebrospinal fluid is from the ventricles to the subarachnoid space, it is doubtful that an appreciable quantity of any medicament introduced into the lumbar sac diffuses to any extent through the subarachnoid pathways. Probably any benefit from therapeutic substances injected intrathecally occurs only after absorption into the blood stream has occurred. Thoughtful consideration of these facts may avoid many tragic neurologic sequelae without depriving the patient of every chance of maximum therapeutic aid.

### SUMMARY

The occurrence of serious neurologic complications following intrathecal administration of many anesthetics, drugs, serums and antibiotics illustrates the grave potential dangers of intrathecal administration. The use of this portal is illogical for most therapeutic agents and may be unnecessary for all. Consideration must be given to whether the benefits obtained outweigh the risk of the grave complications which may ensue.

133 South Thirty-Sixth Street (4) (Dr. George Wilson).

# PREFRONTAL LEUKOTOMY, AN EVALUATION

HARRY C. SOLOMON, M.D.
Boston

## HISTORICAL BACKGROUND

In 1936 Egas Moniz [1] called attention to a brain operation involving destruction of the anterior portion of the frontal lobe in the treatment of the psychoses. He introduced the terms "prefrontal leukotomy" and "psychosurgery" (*psychochirurgic*). Very shortly following the appearance of his monograph, Freeman and Watts began their studies in this country. Although the procedure was soon rather widely practiced, with the exception of the work of Freeman and Watts [2] the number of cases studied was small. The early results which were observed to follow this method of treating psychotic patients were by no means uniform. In many instances considerable objection was raised to the idea that psychotic persons could be benefited by a destructive brain lesion, and the procedure was severely criticized.

The work of Moniz and his followers was not entirely empiric but grew out of a great deal of knowledge about frontal lobe pathology and symptomatology. It followed carefully recorded observations and a great deal of experimental work, particularly that on monkeys by Jacobson and Fulton in New Haven, Conn.[3]

## GENERAL EVALUATION OF OPERATIVE RESULTS

Eleven years' experience has now accumulated and it becomes desirable to make some general evaluations concerning the effectiveness of the operation. It must be borne in mind, however, that there are a number of reasons why it is not easy to arrive at completely satisfying statistics. First, the operative technic varies with the surgeon. The exact amount of medullary substance and cortex that is destroyed is often unknown. The preoperative condition of the patient also varies greatly. What would be considered, in exact sciences, a proper control is not currently available in dealing with these problems of human behavior and mental symptoms. Perhaps at this time the best that can be offered is a general consensus regarding the two major considerations—namely, the benefits from the operation and the defects which follow it.

In the great majority of instances, the operation has been undertaken in patients who were considered chronically ill with a minimal probability of improvement from other forms of therapy. The literature would indicate that, in a small percentage of psychotic cases of this sort, spectacular improvement has occurred, enabling the patients to return to a position of usefulness in society, and to be, at times, self sustaining. This percentage cannot be accurately determined, but a fair estimate would be in the neighborhood of 10 per cent. It may be further judged that another 15 or 20 per cent of patients who undergo prefrontal leukotomy are able to live a relatively happy life and be in part self sustaining. Probably 80 per cent of the patients subjected to this type of surgery become more contented and have a more satisfactory existence than before operation.

The mortality rate from the operation varies considerably from hospital to hospital but may be estimated as in the neighborhood of 3 to 4 per cent—less than that (i. e., 1 to 2 per cent) in those instances in which operation has been performed in a large series of cases and suitable preoperative and postoperative care is available.

The degree of defect that is produced by the operation is as difficult to estimate as are the benefits which follow it. The degree of impairment in psychologic functions is not easy to determine. Since many patients have been ill for years, it is difficult to decide how much of the loss is due to brain injury and how much is a consequence of the condition for which the operation was performed. Tests of general intelligence have not been found to be particularly revealing, perhaps because more specific functions are affected by the operative procedure. In the case of tests of concrete and abstract behavior (tests, that is, of the ability to break up a given whole into parts and to generalize from these parts) impairment occurs but its degree is slight. The Goldstein-Scheerer tests, for example, which measure such behavior, indicate a poorer performance following operation. Results from the Shipley-Hartford Retreat Scale do not permit an unequivocal evaluation of performance. A poor performance following leukotomy is often due to slowness of response and limited cooperation on the part of the patient. There is also a tendency for the patient to give answers which have little bearing on the problem as though, in his opinion, any response would be regarded as adequate.

As for personality tests, the results of the Rorschach test show a greater tendency for the patient who has a leukotomy to repeat responses (perseveration), and his responses are more stereotyped and conventional. However, in the use of color, which is a measure of emotional reactivity, there is greater freedom of response and less rigidity.

Clinical observations indicate that a variety of reactions which must be considered as defects may follow the operation. A carefree attitude, with euphoria, may be excessive for the best of personal relations. Apathy, lack of interest, procrastination, facetiousness, profanity, outbursts of temper and distractability are among other undesirable conditions which have been encountered. There is a distinct tendency for these unfavorable reactions to improve during the course of months fol-

W.: Psychosurgery: Intelligence, Emotion and Social Behavior Following Prefrontal Lobotomy for Mental Disorders, Springfield, Ill., Charles C Thomas, Publisher, 1942; Pain of Organic Disease Relieved by Prefrontal Lobotomy, Lancet **1**: 953, 1946; Psychosurgery During 1936-1946, Arch. Neurol. & Psychiat. **58**: 417 (Oct.) 1947.

[3] Note: Dr. Solomon was requested by the Veterans Administration to describe the rationale of the operation at somewhat greater length and in terms of pathologic physiology. He replied: "In my opinion such a discussion would of necessity be very theoretical and probably completely unsound. I would be better advised not to attempt it."

lowing the operation. The greatest concern is in relation to the loss of some of the important characteristics of personality integration, such as judgment, planning for the future, discrimination, laudable ambition, fine sentiments and creative imagination. These are factors that are not readily evaluated. From a practical point of view, one should be prepared for some defect in these functions when deciding on the advisability of leukotomy.

Convulsive seizures occur in from 4 to 10 per cent of patients who undergo operation. Usually only a few attacks are suffered, but occasionally a patient will have repeated seizures. The electroencephalogram is usually strikingly abnormal in those in whom seizures develop. Abnormalities are accentuated in the anterior regions of the hemispheres and are often focal, being more pronounced on one side than on the other. Focal abnormalities may, however, occur after operation in patients who have no seizures. A marked electroencephalographic dysrhythmia occurs in most patients immediately after the operation but tends to subside within three months. The persistence of abnormality, or the recurrence of abnormality, particularly focal, suggests an epileptic complication.

It may be concluded that leukotomy will lead to some degree of defect but, at the same time, that it is likely to produce results which are beneficial from the standpoint of total behavior. One must then balance the possible assets against the possible liabilities. This requires judgment in each case. No specific and definite rules can be given but only some general suggestions based on the collective experience to the present. This experience indicates the following:

1. Tension, apprehension, fear, concern, worry and agitation are greatly reduced or abolished.
2. Excitement, aggressive and assaultive behavior, emotional outbursts and ragelike exhibitions, although not infrequently intensified shortly after the operation, tend to diminish and disappear within a few weeks or months.
3. Paranoid ideas tend to lessen to the vanishing point or, if continued in an attenuated form, cease to lead to overt expressions.
4. Obsessive thinking becomes less distracting, compulsive actions no longer occur and ritualistic behavior ceases.
5. Long-standing hallucinations may lessen or may lead to a lessened response; only rarely do they disappear entirely.
6. Anergic states are occasionally transformed into states of greater activity but frequently are unchanged, or activity may even be reduced.

## SPECIFIC INDICATIONS FOR OPERATION

On the basis of the foregoing observations, one may discuss, seriatim, the several symptom complexes or disease categories in which leukotomy is to be considered.

1. *The Manic-Depressive Psychosis and Involutional Melancholia.*—Patients falling into the diagnostic groupings of manic depressive psychosis and involutional melancholia who have reached a state of chronicity and who have failed to recover after having the benefit of the best available environmental conditions, psychotherapy and convulsive shock therapy are good candidates for leukotomy. The question of when a chronic state with little expectation of recovery has been reached cannot be categorically decided. Psychiatric judgment of a high order is necessary. When it appears that recovery by other methods of treatment is unlikely, the operation may be said to be advisable.

2. *Obsessive-Compulsive Neurosis.*—Patients with obsessive-compulsive neurosis who have had this syndrome for several years, with an increasing intensity of symptoms progressing toward a state of incapacity, or who are quite incapacitated and wholly miserable, may be considered as candidates for leukotomy. However, one should be reasonably sure that the patient has had the advantage of the best psychotherapy that can be made available before advising operation. It should be borne in mind that obsessive-compulsive symptoms lasting no more than a year or two, with spontaneous remission, are of frequent occurrence; hence, one should not be precipitate in concluding that the patient will not undergo remission. The classic case for which leukotomy is the logical present day treatment is one that begins insidiously in puberty or early adolescence and progresses inexorably for years to incapacity in the middle or the late twenties or in the thirties.

3. *Schizophrenic Psychosis.*—The patients with schizophrenic psychosis are the most challenging of the several groups under discussion. At this stage of our experience with leukotomy and in the present state of our knowledge concerning patients with this diagnosis, a reasonable conservatism should be maintained. One need not be too pessimistic about the probable outcome. A considerable proportion of patients bearing this diagnosis recover or show remissions in the first year of illness, especially those with acute onsets which develop in the presence of a previously adequate adjustment. Convulsive shock therapy and insulin shock therapy, or both combined, add to the percentage of recovery and result in a satisfactory improvement rate.

Few patients, however, recover spontaneously after being ill for more than a year, and after a year of illness neither convulsive nor insulin shock therapies produce a large number of successful results. Certainly after two years of illness, the recovery rate for schizophrenic patients is low, reaching almost the vanishing point. Although there are exceptional patients who recover after two, three or more years of illness, it is unfortunately not possible to predict which will have this exceptional course. It may be assumed that after three years of illness the likelihood of recovery is exceedingly small indeed, and such patients may then be properly considered for leukotomy. Experience has shown that, when operation has been delayed until aften ten years of hospitalization, few patients have been sufficiently improved by it to be able to resume their place in the world outside the hospital. Somewhere, therefore, during the course of illness, there is a critical point before which the leukotomy is worth while and after which it is not advisable. This point in time probably varies with each patient and is therefore difficult to determine. How early in the course of a schizophrenic illness one is justified in concluding that a chronic state has been reached with little chance of recovery, either spontaneously or as the result of shock therapies or of available psychotherapy, is also difficult to state with any precision. In general, it may be stated that a patient ill with a characteristic schizophrenic syndrome who has failed to benefit from good environmental, psychotherapeutic and shock therapies has but a small likelihood of recovery without operative intervention. Somewhere after twelve or eighteen months of properly treated illness the best of psychiatric judgment should be utilized to consider the desirability of leukotomy.

In the present state of medical knowledge, it is not possible to give a definite statement as to the probability of improvement by leukotomy among the various classes within the schizophrenic group, but there are certain types of patients who appear to react more favorably to the operation than others. Patients with a great deal of emotional turmoil, with catatonic-like behavior patterns and with circumscribed paranoid trends appear to have a better prognosis if operated on than the patients with little energy, with little emotional turmoil and with a hebephreniac-like syndrome. Patients who have had a history of good adjustment prior to an acute onset of a psychosis appear to have better prospects postoperatively than those whose symptoms have developed insidiously on the basis of a poor life adjustment.

4. *Paranoid Psychoses.*—The best results from leukotomy are, as a rule, to be observed in patients suffering from paranoid psychoses. Those who are believed to be chronically ill, and in whom psychotherapy and other therapy appear to have failed, constitute a proper group to be considered for operation. Those patients whose paranoid systems are well organized and who maintain good contact with reality tend to make a good readjustment after the operation. On the other hand, persons, sometimes considered to belong to this group, who are disorganized in their thinking processes and subject to vivid and continued auditory hallucinations tend to have a less satisfactory outcome.

5. *Psychosis Associated with Organic Disease of the Brain.*—Patients whose psychosis is associated with organic disease of the brain appear to benefit seldom if at all from leukotomy. The experience with this group is not extensive but seems to indicate that the operative procedure, rather than improving the patient, tends to hasten deterioration. At present it may be said that, with one definite exception, the operation should not be performed on patients with organic disease of the brain; the exception is the patient whose psychosis appears to be related to chronic encephalitis. In this instance, considerable benefit is often to be expected.

6. *Epilepsy.*—As far as is known at present, prefrontal leukotomy does not materially affect the convulsive diathesis. There is, to be sure, a risk of the operation's producing a convulsive focus, but the risk is apparently no greater in patients who have epilepsy than in those who do not suffer from the disease. Perhaps further experience will prove that this statement is not entirely correct; at present, however, it appears that psychoses associated with epilepsy may be considered for operation on the basis of mental symptoms without undue concern about the convulsive diathesis.

7. *Psychopathic Personality.*—There seems to be no strong evidence or experience to prove that leukotomy will benefit the psychopathic person. There have been a few cases reported in the literature in which adverse behavior has been favorably affected, but the greater mass of evidence, small as it is, indicates that the procedure does not lead to better behavior either in the alcoholic addict or in the antisocial group. In fact, there is some evidence that patients with a bad psychopathic history may be even less inhibited after the operation and, therefore, worse in their social interactions.

8. *Intractable Pain.*—Leukotomy presents the possibility of affording relief to certain persons who suffer severe intractable pain, such as that caused by tumor masses, tabetic crises, trigeminal neuralgia and similar painful conditions. If less mutilating procedures are inadequate, leukotomy may well be considered.

9. *Physical Defect States and Suicidal Tendencies.*—Leukotomy may be advisable for psychotic patients who are poor risks for shock therapy or in whom physical overactivity is dangerous to life because of physical defects or such disorders as tuberculosis and heart disease. Similarly, patients with a strong suicidal drive for whom shock therapy is contraindicated may be proper candidates for this operation.

## OPERATIVE APPROACH AND TECHNIC

The operative approach and the technic to be used is a problem for decision by the neurosurgical group and will be discussed here only in the form of a few brief statements. Two definite technics are being widely used, namely, the closed technic advocated by Freeman and Watts and the open technic preferred by Drs. Lyerle, Poppen and Penfield. Partial lobectomies have recently been performed. One point of importance is that there is little uniformity among different operators as to the total amount of white substance cut or of gray matter destroyed. Similarly, it is probable that there is no uniformity as to the exact site at which the surgical destruction is imposed. Some studies have been reported which suggest that adequate benefit may be attained by cutting only the lower quadrants of the anterior frontal region. Some attempts have been made to study the differences which are attained by section made more anteriorly as compared with others made more posteriorly. As yet, however, sufficiently definite conclusions to permit standardization of operative procedure have not been reached.

## POSTOPERATIVE COURSE

The clinical course immediately following the operation varies according to the surgical technic utilized. There are, however, certain general effects that are rather uniform. Immediately following the operation, the majority of patients fall into an inert state in which they appear to be in deep sleep. This is not actually the case, for they are capable of immediate response to mild stimuli. The picture as presented is somewhat like that which characterizes epidemic encephalitis. Patients will show little movement, interest or attention for one, two or three days after the operation; then they gradually become more interested, more active and more alert. Usually the patients will be able to get out of bed on the third or fourth day. Occasionally a patient will insist on getting up the day following operation and will seem none the worse therefor. Uninary incontinence is almost uniform and often continues for several weeks, occasionally for much longer periods. The better preserved the personality is, the shorter does the postoperative incontinence continue. The more attention paid to the patient and the more insistence on his controlling his bladder, the quicker this problem is solved. In most instances, response to paranoid delusions is much diminished immediately following the operation. Many paranoid patients who have previously refused to talk with relatives become quite affectionate when visited. This, unfortunately, leads the relatives to feel that more complete success has been achieved than is actually the case. Many patients become exceedingly outspoken and no longer are considerate or contain within themselves their animosities, antagonisms or resentments. As a result they may become vituperative, use foul and obscene language and show resistance to any suggestions. This is usually a passing phase, although it may last for weeks or months and appears to be on the whole a good prognostic sign rather than the reverse. For several [illegible] many patients appear to be [illegible] are inclined to remain in [illegible] resist attempts to get them out of bed or persuade them into activity. This also is often a passing phenomenon but may last for a number of weeks. A tendency to overeat is frequently encountered. As a rule this is not the result of increased appetite but is due to a lack of judgment or feeling of satiation; if it is not corrected it will lead to excessive gain in weight. Following the operation, patients often become more sociable and more articulate, and it is possible to obtain a much better physician-patient relationship than could be obtained preoperatively.

### POSTOPERATIVE CARE

The problem of careful physical and psychiatric postoperative care is an extremely important one. Most observers believe that a final satisfactory outcome depends to no little extent on the skill used to rehabilitate the patient. However, just what constitutes the best general psychotherapeutic and environmental approach is not so clear. Some believe that returning the patient to his home environment as soon as possible is extremely beneficial, while others believe that a well-organized hospital regimen is preferable. The opportunity for definite psychotherapy is often afforded by continued hospitalization, and it seems probable, though it has not been proved, that this is of great value. For some patients, a minimum of attention in the environment of a large mental hospital, where they are not pushed too hard and where they can slowly take on responsibilities and be put to useful activities without being unduly pressed, appears to be most salutary. It would seem that in this regard, as in others, judgment directed to the individual needs of the particular patient will bring the best effects rather than a routine prescription of a regimented program which is similar for all patients. Complications often arise because of the situation at home. If, for one reason or another, there it no adequate home to which the patient can return, or if the situation at home is changed because of long absence or as a result of emotional and temperamental changes among the relatives, tragic situations may result. When the patient returns home the family need careful advice, continuing guidance and encouragement.

**The First Official Weatherman.**—The first official meteorologic records in America were started April 2, 1814, when Dr. James Tilton, Physician and Surgeon General of the Army, directed Hospital Surgeons to record the weather. The best known meteorologist of the Medical Department is Surgeon Albert James Myer, of New York, who became the first Chief Signal Officer of the Army and founder of the Weather Bureau. Fort Myer, Virginia, is named after him. Surgeon Myer, while stationed in Indian country in 1858, made a study of the Indian system of signaling by beacon lights and smoke signals from mountain tops. His system proved of value in the Civil War. Professor Spenser Fullerton Bair, Secretary of the Smithsonian Institution, induced the War Department to allow Army surgeons to take on the duties of naturalists in their work in the early West. Some of the work of these Army surgeons is unsurpassed in the country's ornithologic history.—Release, Surgeon's General Office, July 1, 1949.

# PROBLEM CASES OF TOXIC DIFFUSE GOITER TREATED WITH RADIOACTIVE IODINE

MYRON PRINZMETAL, M.D.
CLARENCE M. AGRESS, M.D.
H. C. BERGMAN, Ph.D.
and
BENJAMIN SIMKIN, M.D.
Los Angeles

Several investigators [1] have reported the successful use of radioactive iodine in the management of toxic diffuse goiter (Graves' disease). In the published reports, no particular emphasis has been given to this form of therapy in cases of hyperthyroidism in which complications exist due either to the underlying disease or to unrelated illnesses, and which therefore render surgical treatment an inadvisable or risky procedure. Surgical management of most cases of thyrotoxicosis has proved to be satisfactory, but in a few situations it carries a mortality risk or the danger of undesirable surgical complication or gives poor results. Among these surgically unsuitable situations are: (1) patients with multiple recurrences of thyrotoxicosis after previous adequate surgical removal of thyroid tissue, (2) patients with severe congestive heart failure, (3) patients with extreme emotional instability or frank psychosis and (4) patients with unusually severe toxicity difficult or impossible to control by antithyroid drugs or the administration of inorganic iodine preparations.

The purpose of this study is to report that such patients may be successfully treated with radioactive iodine. Eighteen patients with one or another of the aforementioned complications have been treated with radioactive iodine ($I^{131}$) and have been followed longer than one year. It is of interest that the majority of these patients were referred for radioiodine treatment by surgeons who felt that operation was not the treatment of choice or that it carried too great a risk.

### PROCEDURE

All patients were treated with carrier-free radioiodine, $I^{131}$, obtained from the uranium pile at Oak Ridge, Tenn. In early studies [2] mixtures of both $I^{130}$ and $I^{131}$ were used, but the material employed in our study contained no $I^{130}$. $I^{131}$ is the longer-acting isotope, having a half-life of eight days.

To insure maximum uptake of the radioiodine by the thyroid gland, all patients were placed on a low iodine diet and none were treated until the lapse of four to six weeks after any previously administered iodine. Complete medical and laboratory examinations, including plasma organic iodine determinations, were made of all patients preliminary to treatment. Careful follow-up records were kept. In brief the technic, which in most details is that of Soley and Miller,[1d] is as follows:

> The patient was given a small amount of $I^{131}$, usually 0.5 to 1.0 millicurie, in order to determine the uptake of the iodine by the thyroid gland. The material looks and tastes like water and is taken orally. Simultaneously, the same amount of radio-

iodine is placed in a 50-cc. vial and diluted to a total volume of 50 cc. This material serves as a standard for subsequent measurements of radioactivity. The patient returns for measurement within a forty-eight hour period. He sits comfortably in front of a shielded Geiger counter, the opening of which is 29 cm. from the thyroid gland, and the radiation emanating from the region of the thyroid gland is measured; this is the neck count. A count over the thigh is made in order to account for the radioiodine contained in the nonthyroid tissues, and this is subtracted from the neck count, thus giving the amount of $I^{131}$ taken up by the thyroid gland. The count of the standard is also determined at this time, and this is taken as 100 per cent; the factor of decay is thus eliminated.

Thus, the thyroid count divided by the count of the standard gives the percentage uptake of iodine by the thyroid gland. It has been shown that for average weight glands the normal thyroid does not take up radioiodine in excess of 30 per cent.[1d] The patients with untreated toxic diffuse goiter have shown uptakes ranging from 35 to 98 per cent. Previous studies[3] have shown that the thyroid uptake is maximal in forty-eight hours. In follow-up observations, usually at monthly intervals, further uptake studies were performed as a guide to adequate dosage. Because of previously reported radiation sickness, dosage was administered cautiously at first, but more boldly as it was found that no untoward reactions resulted. At present the total dosage required by any patient is a matter of clinical judgment. The patients in this study received total doses of $I^{131}$ ranging from 1.5 to 14.5 millicuries and averaging 5.3 millicuries. Even with the larger doses radiation sickness did not occur. Our earlier treated patients were often given radioiodine several times before a euthyroid state was reached, but, as experience has grown, the number requiring more than the initial calculated dose has greatly decreased.

*Summary of Results in 18 Cases of Complicated Toxic Diffuse Goiter*

* Micrograms per hundred cubic centimeters.

A total of 18 cases comprise the basis of this study (table). All but 1 have been followed from twelve to eighteen months. There were five types of complications: (1) congestive heart failure (3 cases), (2) extreme emotional instability or psychoses (3 cases), (3) extreme toxicity (3 cases), (4) recurrence of thyrotoxicosis after previous thyroidectomy (8 cases) and (5) thyroid malignancy (1 case).

## RESULTS

1. *Congestive Heart Failure.*—There were 3 cases in this group. In all there was a complete response to therapy with subsidence of toxicity and recovery from failure. One patient with associated coronary disease later had an acute myocardial infarction, from which she also recovered.

[3] Hamilton, J. G., and Soley, M. H.: Studies in Iodine Metabolism of the Thyroid Gland in Situ by the Use of Radio-Iodine in Normal Subjects and in Patients with Various Types of Goitre, Am. J. Physiol. 131: 135 (Nov.) 1940.

The following case illustrates the excellent response to radioiodine therapy manifested by a patient with severe congestive failure (fig. 1).

Case 2.—E. B., a 65 year old white housewife, had been troubled with palpitation and nervousness for over two years. During the year prior to examination she suffered from shortness of breath on slight exertion and growing weakness. Sometimes dyspnea occurred at night, waking her from her sleep. In spite of an increased appetite, she had lost over 40 pounds (18 Kg.) in weight in six months.

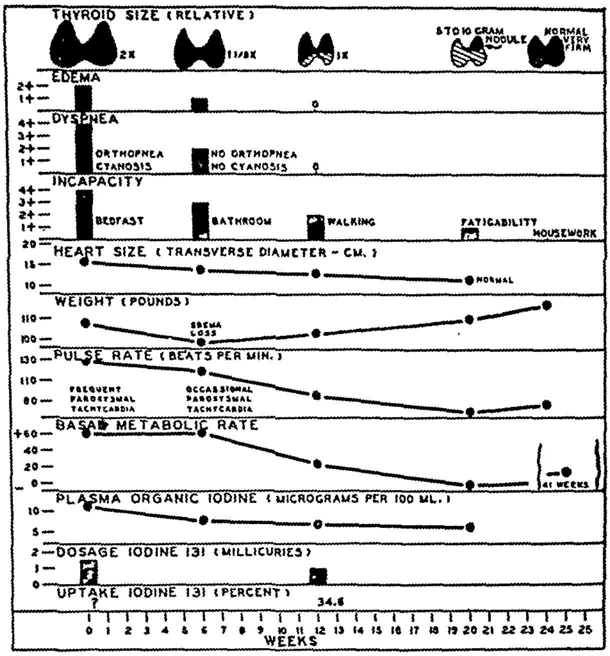

Fig. 1.—Illustrative case of thyrotoxicosis complicated by congestive heart failure (case 2). This 55 year old white woman was completely incapacitated with severe heart failure. Thiouracil had caused leukopenia, and she was considered too ill to withstand operation. Complete remission occurred following radioactive iodine therapy.

On Aug. 24, 1946, she had an acute episode of precordial pain, accompanied with dyspnea and cyanosis, requiring morphine for relief, and was hospitalized by her private physician because of acute left heart failure. An electrocardiogram showed an auriculoventricular nodal tachycardia, which was controlled with digitalis. A roentgenogram of the chest showed an increase in the transverse diameter of the heart with rapid forceful pulsations. There was moderate passive pulmonary congestion. No substernal thyroid gland was present.

An electrocardiogram, Sept. 2, 1946, showed a normal rhythm, with a rate of 90, and left ventricular strain. There was some peaking of the P waves. At this time an orthocardiogram showed a decrease in the heart size with clear lung fields. Further study now revealed a basal metabolic rate of + 65 per cent. She was given thiouracil, 0.2 Gm. twice daily. This was discontinued after two days because of a drop in the white blood cell count.

After this the patient's symptoms became more and more aggravated, and she was referred to a surgeon for removal of her thyroid gland but was considered too poor a risk for operation. She was therefore referred to Cedars of Lebanon Hospital for radioactive iodine therapy on September 30. Physical examination showed the temperature to be 98 to 99 F., height 65 inches (165 cm.), weight 108 pounds (49 Kg.). Her pulse rate varied from 110 to 130; her blood pressure averaged 120 systolic and 70 diastolic. She was poorly nourished, with evidence of severe weight loss. She was extremely apprehensive, and it was almost impossible for her to remain at rest. Eye examination showed loss of convergence, but no lid lag or proptosis. She was dyspneic, orthopneic and slightly cyanotic at bed rest. Her thyroid gland showed enlargement of the left lobe to about twice normal size. It was firm in consistency, and there was no bruit. The neck veins were prominent. Her heart was enlarged to the left, with a heaving apex impulse. There was a systolic precordial murmur of grade 2 intensity, loudest at the apex. A systolic gallop was present. The rhythm was regular. The heart tones were of fair quality. The skin was warm and moist, with flushed palms. There was a coarse tremor of the outstretched fingers, but no tongue tremor. There was edema (2 plus) of the ankles and legs. Laboratory examination showed a basal metabolic rate of + 61 per cent. The plasma organic iodine was 11.7 micrograms per hundred cubic centimeters. Circulation time was 27½ seconds with saccharin and 10 seconds with ether. The urine was normal except for a trace of albumin. Treatment with digitalis, 1½ grains (0.10 Gm.) a day, was continued and the patient was given a 5,000 calory low salt diet with phenobarbital, 1 grain (0.06 Gm.), three times a day, for sedation. On October 1, the patient was given 1.5 millicuries of $I^{131}$. No uptake studies were done, as the patient was too ill to be moved about.

The patient was discharged from the hospital and was subsequently followed up by her private physicians. Her basal metabolic rate on November 16 was + 62 per cent, but by November 25 it had fallen to + 24 per cent, and her cholesterol was 176.5 mg. Her plasma organic iodine had fallen to 8.0 micrograms per hundred cubic centimeters. A recheck roentgenogram showed decrease in the heart size with clear lung fields.

The patient was seen again on December 27, and her weight was now 102½ pounds (46.5 Kg.). She had had a further episode of the paroxysmal tachycardia in spite of the daily dose of digitalis, and the electrocardiogram still showed left strain. However, in the last month her dyspnea and edema had disappeared. She was able to sleep at night, ate well and was gaining strength. A nodule was still palpable on the left side of the neck.

On Jan. 5, 1947, 1 millicurie of $I^{131}$ was again administered. The thyroid uptake at 48 hours was 34.6 per cent. The patient returned for a check on February 14, at which time her weight was 110 pounds (50 Kg.) and her pulse rate 80. She felt strong, had more ambition, noticed increased strength in her legs and was no longer troubled with palpitation. All symptoms of congestive failure had disappeared. At this time, careful palpation of the thyroid gland showed the enlargement on the left side to have completely disappeared; however, a small 2 to 3 cm. nodule, weighing approximately 5 to 10 Gm., was palpated in the right lobe. Digitalis therapy was stopped. The

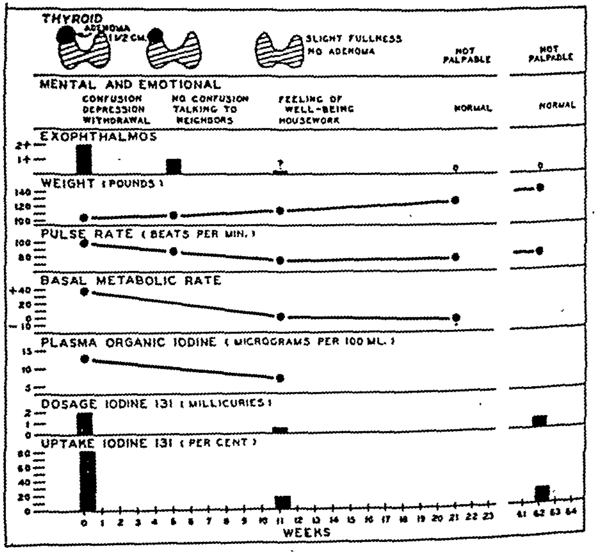

Fig. 2.—Illustrative case of a 65 year old Chinese woman with severe psychosis resulting from toxic diffuse goiter (case 4). Leukopenia occurred after treatment with thiouracil. There was only slight improvement with the administration of strong iodine solution. Her psychiatrist felt that she was a poor surgical risk because of her mental condition. After radioactive iodine therapy, her psychosis completely disappeared, and at the time of last examination, the patient appeared to be entirely well.

level of plasma organic iodine was 6.1 micrograms per hundred cubic centimeters, and her basal metabolic rate had fallen to — 1 per cent.

The patient was seen for the last time on March 18; her pulse rate was 88; her weight was 117 pounds (53 Kg.), and, in her own words, she "felt wonderful." She was symptom free. The thyroid gland showed diffuse slight enlargement of both lobes, rather firm in consistency, but there were no nodules.

2. *Extreme Emotional Instability or Psychosis.*—There were 3 cases in this category. Two of the patients had been referred to psychiatrists and were considered so unstable that their families were advised against surgical treatment. It was for this reason that they were referred for radioiodine therapy; both patients made a complete recovery, with return to mental health. The third patient, the mother of a physician, was frankly psychotic and made an excellent recovery following the administration of radioactive iodine (fig. 2). This last case illustrates the good response to radioiodine therapy encountered in this group.

CASE 4.—M. L., a Chinese woman aged 65, mother of a physician, was first seen on Jan. 3, 1947, with symptoms of loss of 30 pounds (14 Kg.), moderate exophthalmos, pronounced nervousness and recurrent diarrhea of 6 to 8 watery stools a day, all of three years' duration. She also suffered from attacks of palpitation with a feeling of increased heat. Her son, an ophthalmologist, noted prominence of the eyes on his return from overseas and found colloid retinal degeneration.

During this period she had changed from a cheerful, rather phlegmatic housewife to a depressed nervous person who was becoming more and more confused. She refused to do her work and would no longer receive her friends or speak to her neighbors.

A diagnosis of thyrotoxicosis was made, and she was given thiouracil in August 1946. This was discontinued after six weeks because of leukopenia. She also received strong iodine (Lugol's) solution with only slight improvement.

Examination in January 1947 showed a thin, depressed, agitated woman with a resting pulse rate of 100. With any excitement it would increase to 140 or over. Her blood pressure was 140 systolic and 70 diastolic. There were no cardiac abnormalities. There was exophthalmos (2 plus) with very poor convergence and decided lid lag. The fundi showed colloid degeneration. The thyroid gland was slightly full, but the only real abnormality was a firm adenoma measuring 1.5 cm. in diameter at the right upper pole. Except for tremor and warm moist skin, the results of the remainder of the physical examination were normal. The results of laboratory studies are shown in figure 2, as is the subsequent course following the administration of 2 millicuries of radioiodine. She made a rapid and complete recovery in three months, including the disappearance of all mental symptoms. The result of her last uptake study, on March 15, 1948, was 21.2 per cent, and she was still feeling completely well about fourteen months after radioiodine therapy had been instituted.

3. *Extreme Toxicity.*—In this group there were 3 cases. The poorest results in this series were obtained with these cases. Because of the difficulties encountered in this group each of the cases will be described in detail. One patient (case 7), who had a toxic adenoma, received 11 millicuries of $I^{131}$ without any therapeutic response. This was the only frank therapeutic failure in the series reported here.

CASE 7.—Mrs. M. N., a 34 year old white woman, first noticed thyrotoxic symptoms in Germany in 1935. At this time she noted palpitation, weakness, nervousness and weight loss. In a German concentration camp she lost 72 pounds (33 Kg.). She came to the United States in 1946, where a physician found her basal metabolic rate to be + 97 per cent, with a level of organic iodine in the plasma of 14.0 micrograms per hundred cubic centimeters. She was given iodine with considerable improvement, but remained chronically ill. Because of her age and the severity of her toxicity she was referred for radioiodine therapy on Feb. 3, 1947. Examination disclosed a very apprehensive and emaciated patient weighing 101 pounds (46 Kg.), 50 pounds (23 Kg.) under her normal weight. Her pulse was thready and the rate averaged 128. Her blood pressure was 170 systolic and 90 diastolic. There were no eye signs, but pronounced tremor of the tongue and extremities were present. The thyroid gland contained a small 1.5 cm. firm nodule in the right lobe but was not otherwise enlarged. The heart was not enlarged, but the tones were tic-toc in quality. Laboratory study showed a basal metabolic rate of + 90 per cent, a level of organic iodine in the plasma of 14.0 micrograms per hundred cubic centimeters and normal blood cell count and urine. The electrocardiogram showed flattened T waves in standard leads 1 and 4 CF.

On February 20, she was given 2 millicuries of $I^{131}$ with an uptake of 37 per cent. Another 3 millicuries were given in March, 1 millicurie in April and 5 millicuries in June—a total of 11 millicuries. The last thyroid uptake was 47 per cent. During these six months there was no real improvement. She had gained 8 pounds (4 Kg.), but auricular fibrillation had developed and she had a persistent pulse rate of 120 and remained excessively nervous and apprehensive. Also, the thyroid nodule, probably an adenoma, had not changed in size. She was advised to have the adenoma removed but refused. Therefore, she was given propylthiouracil and was making a gradual improvement when referred back to her family physician.

The second patient (case 8) was of unusual interest in that a slow but good therapeutic response was obtained by the administration of 14 millicuries of $I^{131}$ in the face of a severe degree of hyperthyroidism associated with a goiter estimated to be 90 Gm. in weight. After the patient became euthyroid, schizophrenia developed.

CASE 8.—Miss J. C., a 33 year old white woman, had been ill for four years beginning in 1942. On Oct. 6, 1946, the patient entered Cedars of Lebanon Hospital complaining of weakness, nervousness, palpitation, weight loss, swelling of the neck and dyspnea.

At the age of 14 she first noticed a diffuse swelling in the neck, which at that time was diagnosed as a simple goiter. In the ensuing years the goiter regressed, although the patient was conscious of swelling of the neck during menstrual periods. Until 1942 she felt fairly well, her average weight being 145 pounds (66 Kg.). She had been working very hard and noticed an increase in the neck size, weakness, decided nervousness, palpitation, protrusion of both eyes and loss of 20 pounds (9 Kg.). Occasionally she was aware of ankle swelling coming on in the evening. Her appetite was much increased; her skin was always moist and warm, and occasionally she suffered severe sweating. Dyspnea had been present for several months on slight exertion. In the previous two months she had noticed orthopnea and required the use of two pillows for sleep. In the previous year, also, her menstrual flow had become more scanty. Her family history was irrelevant, and review of symptoms revealed no further complaints.

Her past history was normal except that about six years previously she had had a "nervous breakdown." However, she had made a satisfactory recovery, and, while her appearance was unattractive and she remained unmarried, she was cheerful and got along well with her family and the neighbors. She was admitted at this time because of increase of symptoms and was to be prepared for operation.

Physical examination showed a well developed, fairly well nourished, apprehensive patient, weighing 127 pounds (58 Kg.). There was moderate exophthalmos of both eyes and pronounced lid lag. There was a tremor of the tongue, and the mucous membranes of the mouth were red and "beefy" in appearance. The girth of the neck was 13½ inches (34 cm.). There was diffuse enlargement of the thyroid gland, more pronounced on the right side, approximately three and a half times normal size with an estimated weight increase of about 75 to 100 Gm. The tumor was smooth and fairly firm, and over it could be heard a moderately loud blowing systolic and diastolic bruit. The lungs were clear. The heart showed questionable enlargement to the left with a forceful apex beat. Pulse was regular, with rate of 120 at rest. Blood pressure was 170 systolic and 70 diastolic, and there was a presystolic murmur at the apex. No thrill was present. The extremities were entirely normal except for slight pitting edema of the ankles.

The basal metabolic rate was + 46 per cent and, four days later, + 48 per cent. Plasma organic iodine was 20.0 micrograms per hundred cubic centimeters and cholesterol was 173 mg. per hundred cubic centimeters. The urine and blood cell count were normal. A roentgenogram of the chest showed moderate left ventricular hypertrophy with clear lung fields and no substernal thyroid. The electrocardiogram showed sinus tachycardia with some peaking of the P and T waves, but no other abnormalities. Circulation time with ether was 3 seconds and with calcium gluconate 9 seconds. The sedimentation rate was 6 mm. per hour.

The surgical consultant felt that the patient was too toxic for operation, and she was referred for radioactive iodine therapy. On Oct. 8, 1946, she received 1.5 millicurie of $I^{131}$ with an uptake in 48 hours of 77.7 per cent.

She was next seen on November 21. She weighed 141 pounds (64 Kg.), having gained 14 pounds (6 Kg.). She was still nervous, requiring barbiturates for sedation. Her eyes appeared less staring. Her menstrual flow was still scanty and somewhat delayed. Lid lag, tongue tremor and tachycardia were still present; the pulse rate averaged 140. The blood pressure was 210 systolic and 90 diastolic, and the neck measured 14 inches (36 cm.) in girth, the thyroid appearing essentially unchanged, and there was a loud bruit. On December 20, she weighed 144½ pounds (65.5 Kg.), and it was found that her plasma organic iodine was still 20 micrograms per hundred cubic centimeters. Diarrhea had been present from time to time, and her appetite was becoming poor. There was no real improvement. On Jan. 3, 1947, she was given 3 millicuries of $I^{131}$, with an uptake of 88 per cent. Recheck on January 31 showed auricular fibrillation at a rate of 125 to 150. Otherwise the electrocardiogram showed no remarkable changes. Digitalis therapy was started, but the heart rate could not be brought below 100 to 105, in spite of full digitalization. Her blood iodine was again determined and this time showed 21 micrograms per hundred cubic centimeters of plasma. In spite of vitamin therapy, her mucous membranes still showed evidence of severe avitaminosis. Ankle edema persisted; her weight dropped to 136½ pounds (62 Kg.), and she continued to be very nervous and apprehensive. It was felt that she had been given much too small a dose of radioiodine for the large amount of hyperplastic thyroid tissue present, and on February 20 she was given 5 millicuries of $I^{131}$, with an uptake of 98.6 per cent. On March 19, her weight was still 136 pounds (62 Kg.), the apical rate persisted at about 128 and there was no objective evidence of improvement except that the gland had become much firmer. On the following day, March 20, she was given 5 millicuries of $I^{131}$, with an uptake of 53.2 per cent. By April 14, definite evidence of improvement had appeared. Her weight was now 146½ pounds (66.4 Kg.). Her gland was very firm, but about two thirds of its previous size. The neck now measured 13 inches (33 cm.) in girth. Her strength improved, and she was doing a little housework. Her tremor was much less and protrusion of the eyes noticeably decreased. On April 29, her weight was 147 pounds (67 Kg.) and there was still fibrillation, but at the rate of 80 to 100 per minute. The gland was only one third of its former size, very firm and without a bruit. Her skin was dry, and ankle edema had disappeared. Her strength had returned. Exophthalmos was only slight, and her tremor had disappeared. However, in spite of the decided physical improvement, which was confirmed by a level of blood iodine of 6.9 micrograms per hundred cubic centimeters, she had become very panicky and felt that she was about to die and had appeared at the office to tell everyone "goodbye." She was therefore referred to a psychiatrist, who decided that she had a schizoid personality and that her symptoms were the result of her fear of getting well when she would no longer be an object of solicitude for her family and she would have to face reality again. Within a week hallucinations developed and she was institutionalized. For six weeks she was frankly psychotic and was treated with mild insulin shock. During this time, auricular fibrillation persisted and quinidine was given in moderate doses without effect. Right lobar pneumonia developed, but the patient recovered promptly with penicillin therapy and showed no evidence of heart failure. She was returned to her family in a clear mental state but was very unstable. At this time her thyroid gland was only slightly enlarged and very firm. She showed no evidence of toxicity. However, fibrillation continued. At this point she refused further care and dropped out of sight.

Three months later she died suddenly, while running to answer the door bell. She apparently had been sleeping, was startled by the bell, ran to the door and died on the way. She had been taking no medicine except digitalis, which she gave herself when her pulse rate became too fast. She had been doing the housework and gardening, had remained cheerful and showed no evidence of heart failure.

At autopsy the thyroid gland was small but very fibrotic. The heart was dilated and flabby, especially on the right, but there were no other lesions found in any of the organs. No definite cause of death was determined at necropsy.

The third patient (fig. 3) was interesting because of her decided toxicity, her failure to respond to many other forms of management, her inability to be prepared for operation, and her slow response to radioiodine therapy. At the time of last examination she had still not obtained a complete remission, but was decidedly improved, holding a job and troubled only by occasional attacks of palpitation. At the time of writing, treatment was still being continued, and it was felt that her initial treatment was too cautious. Radioiodine at least produced the greatest benefit of the many procedures tried.

Case 9.—Miss V. D'I, a 32 year old white woman, was first seen at Cedars of Lebanon Hospital in January 1946, with complaints of fatigue, dyspnea, nervousness and enlarging tumor in the neck for the previous eighteen months. In the preceding six months protrusion of both eyes developed. She had taken strong iodine solution for one to two months with moderate improvement and a gain of 12 pounds (5 Kg.) in weight.

Examination showed a fairly well nourished woman weighing 129 pounds (59 Kg.), very nervous, with exophthalmos (3 plus) bilaterally, slight edema of the lids, acneiform eruptions of the face, pronounced lid lag and poor convergence. Her skin was warm and moist, and there was a fine tremor of the extremities. Her pulse rate averaged 120 at rest, and her blood pressure was 170 systolic and 80 diastolic. The heart was normal except for a blowing apical systolic murmur, and there were no signs of congestive failure. The thyroid gland was soft, diffusely enlarged to about three times normal size, and there was a systolic bruit audible over it.

Laboratory studies revealed a normal blood cell count and normal urine. Plasma organic iodine was 11.0 micrograms per hundred cubic centimeters and serum cholesterol 256 mg. per hundred cubic centimeters. Several basal metabolism tests were made, and the rate averaged + 75 per cent. Results of tests of hepatic function were normal, and the electrocardiogram showed only sinus tachycardia. On fluoroscopic examination the heart appeared overactive.

The patient was given strong iodine solution, 30 drops daily. After one month this therapy was stopped because of lack of a satisfactory response, and in March she was given 6-propyl-2-thiouracil, 25 mg. three times a day. After eight months of therapy, with up to 200 mg. daily, there was no satisfactory response and the medication was discontinued. In October roentgen therapy over the gland was given when the propylthiouracil therapy was stopped. In January 1947, she was rehospitalized because of the continued severe toxicity and failure of therapy. She was exceedingly apprehensive and in constant motion. Her teeth had become carious. At this time her plasma organic iodine was 14.0 micrograms per hundred cubic centimeters and her pulse rate averaged 120, basal metabolic rate + 70 per cent, weight 118 pounds (54 Kg.) and serum cholesterol 201 mg. per hundred cubic centimeters. She was believed to be too toxic for operation and was referred by the thyroid committee for radioiodine therapy.

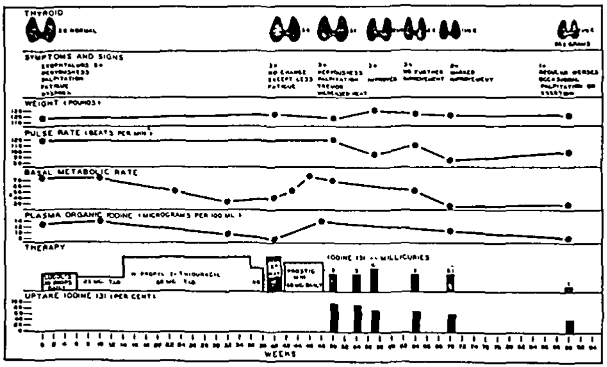

Fig. 3.—Illustrative case of a 32 year old white woman with severe thyrotoxicosis (case 9). She received fifty weeks of treatment with (Lugol's) strong iodine solution, propylthiouracil, roentgen rays and neostigmine (prostigmin®). During this fifty week period she was considered too toxic for operation and was therefore referred for radioactive iodine therapy. There was great improvement, and the patient was able to return to work. Although it is felt that this patient is not completely cured, radioactive iodine gave her more benefit than any other form of treatment.

On January 3, she received 3.0 millicuries of $I^{131}$, with an uptake of 97.5 per cent. On February 20, she was given 3.0 millicuries, with an uptake of 91.7 per cent. On April 17, she received 4.0 millicuries, with an uptake of 76.0 per cent. Her weight on April 22 was 132 pounds (60 Kg.) and pulse rate 96; she was less nervous and was felt to be improving. On June 24, she weighed 126 pounds (57 Kg.), her basal metabolic rate was + 54 per cent and her pulse rate 112. On July 19, she again received 3.0 millicuries, with an uptake of 74.4 per cent. On October 25, she was given 3.1 millicuries and her uptake was 62.4 per cent. The level of iodine in the blood on October 27 was 11.2 micrograms, and her basal metabolic rate was + 27 per cent. On November 25, she weighed 123 pounds (56 Kg.), her pulse rate was 86, her gland was much smaller and she felt much better. On December 23, she weighed 120 pounds (54 Kg.), her pulse rate was 78 and she felt fine. On March 12, 1948, she received 1.0 millicurie and her uptake was 44.7 per cent. The level of iodine in the blood at this time was 8.4 micrograms, and the basal metabolic rate was + 31 per cent. On March 15, her thyroid gland weighed approximately 35 Gm., her pulse rate was 100 and she weighed 123 pounds (56 Kg.). She was getting along without sedation, her menstrual periods were regular and she noticed only occasional palpitation on exertion. She was not working at this time. At the time of last examination, she was still not cured but was decidedly improved, holding a job and troubled only by occasional attacks of palpitation. Treatment is still being continued. It is felt now that her initial treatment was too cautious. Radioiodine at least produced the greatest benefit of the many procedures tried.

Thus, in this group of 3 cases, a complete remission of the thyrotoxicosis was attained in 1 case, a partial remission in another, and no improvement was obtained in the third.

4. *Recurrence of Thyrotoxicosis After Previous Thyroidectomy.*—Eight cases comprised this group. Four of the patients suffered recurrence of hyperthyroidism after two operations and 2 patients relapsed after each had undergone four thyroidectomies. Three patients in this group had failed to respond to previous courses of therapy with both thiouracil and deep irradiation over the thyroid gland. There were 2 patients who had recurrences after one previous thyroidectomy. One of these (case 10) had hemorrhaged so severely after hemithyroidectomy that further surgical treatment was abandoned and she was referred by her surgeon for completion of treatment with radioiodine. The other patient (case 11) had undergone operation eight years previously with prompt return of symptoms followed by a chronic course of moderate thyrotoxicosis with auricular fibrillation. A state of extreme malnutrition had developed, and the patient had escaped congestive failure by greatly limiting his activities and dosing himself with iodine from time to time. A patient, L. K. (case 12), was referred by her surgeon not only because of recurrence after two previous operations but because the remaining thyroid tissue was cartilagenous in consistency and it was felt not to be amenable to further operation. With treatment her toxicity was completely controlled and the thyroid tissue softened and nearly disappeared. However, her right eye began to show progressive exophthalmos, the only patient in our series whose exophthalmos became worse. At the time of writing, the exophthalmos was improving with thyroid medication.

The following case illustrates the excellent response to radioactive iodine of a patient with severe thyrocardiac disease who had had four recurrences of thyrotoxicosis following as many subtotal thyroidectomies (fig. 4).

CASE 13.—W. W., a 55 year old white man, had thyrotoxicosis while in the Navy, and a thyroidectomy was performed in 1930. Because of recurrences of hyperthyroidism he had three more thyroidectomies, in 1931, 1932 and 1944. He was improved only a few months following the fourth operation and entered Cedars of Lebanon Hospital in November 1946 complaining of recurrence of nervousness, dyspnea, palpitation, increased heat and swelling of the ankles, for which he had been given irregular medication with digitalis.

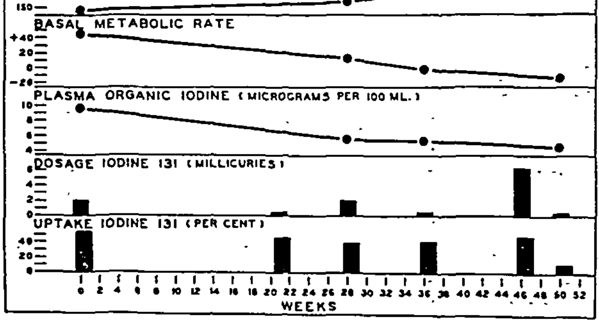

Fig. 4.—Illustrative case of recurrence of thyrotoxicosis following four subtotal thyroidectomies. The patient had refused a fifth operation (case 13). This case was complicated further by congestive heart failure. Following the administration of radioactive iodine, the cardiac decompensaton completely disappeared and the patient, at the time of last examination, appeared to be entirely well. (FBD is fingerbreadths.)

Physical examination revealed moderate dyspnea and orthopnea; the pulse rate was 160 and irregular; the blood pressure was 130 systolic and 80 diastolic. Exophthalmos was questionable. However, the thyroid gland contained a walnut-sized nodule in either lobe, an estimated total weight of 50 Gm. At irregular intervals the cardiac rhythm was irregular. There were moist rales in the lung bases, and the liver was enlarged 2 fingerbreadths below the right costal margin. However, the extremities showed no edema or tremor.

Laboratory study showed the basal metabolic rate to average about + 45 per cent, plasma organic iodine 9.7 micrograms per hundred cubic centimeters and serum cholesterol 188 mg. per hundred cubic centimeters. The electrocardiogram showed an auricular flutter with an auricular rate of 315. A roentgenogram of the chest revealed normal cardiac silhouette and clear lung fields. The patient was digitalized, but the rate could be slowed to only 90. At this time the electrocardiogram revealed auricular fibrillation. The patient refused surgical treatment, and he was first given 2.0 millicuries of $I^{131}$ in February 1947, retaining 54 per cent in the thyroid gland after 48 hours. By May his basal metabolic rate was + 12 per cent and plasma organic iodine 5.5 micrograms, and he felt somewhat improved. He was given another 2.0 millicuries, this time with a 39 per cent uptake. His gland was only slightly enlarged, and no nodules were palpable. His pulse rate was 86. He was still very nervous. No evidence of heart failure was present, and he stated that he "rarely took digitalis." In September, a tracer dose still showed an uptake of 40.6 per cent, but his basal metabolic rate was — 2 per cent and blood iodine 5.3 micrograms. The gland was only slightly enlarged; the pulse rate was regular at 80; he had gained 10 pounds (5 Kg.) and stated that he felt very well. The last uptake study was done on March 15, 1948 with a reading of 11.2 per cent, and at this time the patient felt well. His plasma iodine was 4.5 micrograms.

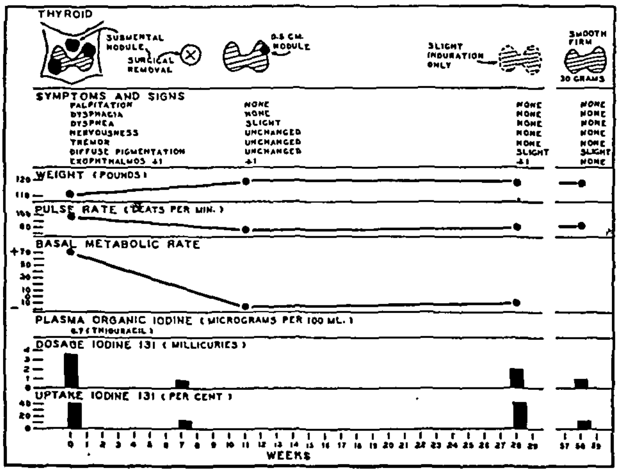

Fig. 5.—Illustrative case of a 51 year old woman with functioning *papillary adenocarcinoma of the thyroid with hyperthyroidism (case 18).* She had had three recurrences following operation and roentgen therapy. After the use of radioactive iodine there was a prolonged remission of the hyperthyroidism and the nodules in the gland, presumably malignant, were no longer palpable.

In this group, therefore, all patients previously shown to have recurrences after two to four operations, had been restored to a euthyroid state and had so remained for twelve to eighteen months. Whether the rate of recurrence in this group after radioiodine therapy will be as high as after surgical treatment remains to be determined. At least radioiodine is a useful method of treatment in this type of problem.

5. *Thyroid Malignancy.*—Several cases of thyroid malignancy treated successfully with radioiodine have been reported, but the great majority of patients do not respond, largely because malignant tissue only rarely retains radioiodine in therapeutic quantities. Only 1 patient with thyroid malignancy has been treated in our series. The history was unusual, since the histologic diagnosis of carcinoma of the thyroid gland was first made in 1927 when the patient presented herself to her physician with signs and symptoms of thyrotoxicosis. She subsequently had three thyroidectomies because of recurrence of thyrotoxicosis. Each time the histologic diagnosis of the removed thyroid tissue was "papillary adenocarcinoma of the thyroid." She was seen by us in 1947 because of another recurrence of hyperthyroidism. Moreover, a metastatic nodule in the neck was found. No other metastases were found. Treatment consisted of a combination of surgical removal of the metastatic nodule and the administration of radioiodine with consequent remission of the thyrotoxicosis. The details of this case (fig. 5) follow:

Case 18.—Mrs. H. Q., a 51 year old white woman, was first seen on Dec. 16, 1946, complaining of recurrent goiter. She had been cared for by Dr. Charles T. Sturgeon of Los Angeles since the onset of the disease in 1925. Her original symptoms were characteristic of thyrotoxicosis: weakness, loss of weight, tachycardia, nervousness, nausea, stiffness of the leg muscles, tremor, sweating and enlargement of the thyroid. A goiter had been present in the neck in the form of a 1 cm. nodule since the age of 16 but had given no trouble until the patient was 25 years old, when it rapidly increased in size to the accompaniment of the aforementioned symptoms. A subtotal lobectomy was performed on June 8, 1925. The left lobe contained a large nodule 4 cm. in diameter and several smaller nodules. The right lobe appeared normal. Diagnoses from section of the tissue were: (1) toxic adenoma of the thyroid and (2) papillary adenocarcinoma of the thyroid.

Dr. Sturgeon reported that the patient made an excellent recovery and was not seen again until Oct. 28, 1934, when there was a recurrence of the symptoms present in 1925, with enlargement of the right lobe of the thyroid. He stated that the patient had severe hyperthyroidism.

In 1927 the diagnosis was hyperthyroidism, and the patient underwent subtotal thyroidectomy. Pathologic study revealed a papillary adenocarcinoma. The slides were reviewed by Dr. Roy Hammack of Los Angeles and by Dr. Broders of the Mayo Clinic, and they concurred in the diagnosis. At this time the patient also received extensive irradiation of the gland. She remained well until October 1934, when she again showed hyperthyroidism with enlargement of the right lobe and pronounced exophthalmos for the first time. On this occasion Dr. Sturgeon performed an "almost total thyroidectomy." Again the diagnoses from pathologic study were: (1) hyperplastic goiter and (2) papillary adenocarcinoma of the thyroid. She was given an extensive course of roentgen therapy.

In 1936 a small nodule recurred in the scar and was removed. In 1937 a 2 cm. nodule was removed from the left breast. Tissue study showed no malignancy. In 1946 the patient was under the care of Dr. Matousek of Glendale, Calif. She had consulted him for rapid irregular heart action, choking feelings, difficulty in swallowing, a feeling of warmth to burning with decided itching, severe dyspnea on exertion, weight loss, nervousness and lumps in the side of the neck. Two basal metabolism tests showed elevated values of + 85 per cent and + 65 per cent. On Oct. 15, 1946, treatment with thiouracil, 0.6 Gm. daily, was started. By December 6 her basal metabolic rate had fallen to + 26 per cent and she felt improved.

Review of the past history further revealed that she had had some type of tumor of the navel removed fifteen years previously. There was a high incidence of cancer in the family, and her mother had had a goiter.

Physical examination showed a small, well developed, undernourished white woman. Her face was thin, with a staring expression due to the slight exophthalmos, and there was a striking dusky blue pigmentation of the skin of the entire body which had been noticed for about a year. Lid lag was pronounced, and convergence was impaired. The lips were cyanotic or pigmented. Three discrete 2 by 3 cm. nodules were present in the neck. The largest was in the submental space in the midline and was not attached to the thyroid gland. The other two were on each side of the trachea in the thyroid area. All were discrete, firm and visible as well as palpable. Old operative scars were, of course, present. Dry rales were heard in both apexes. The heart was slightly enlarged to the left and the rhythm regular. There were systolic murmurs both at the pulmonic and mitral areas. Except for a slight tremor of the outstretched fingers, the results of the examination were otherwise normal.

Laboratory study showed: hemoglobin 80 per cent, red blood cells 4,460,000 and white blood cells 7,300, with 70 per cent polymorphonuclear cells, 28 per cent lymphocytes and 2 per cent transitional forms. The electrocardiogram showed sinus rhythm, with no remarkable changes except that the P waves were peaked. The plasma organic iodine was 6.7 micrograms per hundred cubic centimeters and phosphatase (alkaline) 6.4 Bodansky units.

On Jan. 3, 1947, thiouracil therapy having been discontinued on Dec. 25, 1946, she was given 1 millicurie of $I^{131}$, with retention of 40.5 per cent. This amount was used only as a tracer dose, and on January 8 she was given an additional 2.4 millicuries.

On February 11 she was much improved. She had gained 4 pounds (2 Kg.), was no longer dyspneic and did not have palpitation. Her nervousness had decreased. However, there were no changes in the eye signs. The nodules were unchanged. On February 20 she was given 0.77 millicuries, with an uptake of only 6.7 per cent.

Examination on March 19 showed that she had continued to gain weight, had a pulse rate of only 76 and "continued feeling better." However, she was still nervous. Early in March 1947 Dr. Sturgeon removed the submental nodule. Study of this tissue showed: chronic thyroiditis, a few focal areas of hyperplasia and definite evidence of malignancy. An uptake study on the surgically removed tissue gave a value of 1.7 per cent; the tissue weighed 2.65 Gm.

The most remarkable change in the patient was that the nodule on the right had completely disappeared and the one on the left was just palpable. The body of the gland could be faintly outlined now because of its firm character. The basal metabolic rate was now —16 per cent. Her improvement was followed until August, when she was given another 3.5 millicuries, this time with an uptake of 42 per cent. However, no real thyroid enlargement was palpable in the neck, her pulse rate was 80 and weight 118 pounds (54 Kg.) and all her symptoms had disappeared except flushing, which was attributed to menopausal changes. She stated that she felt better than she had at any time in the previous twenty-three years. A final uptake study was made on March 15, 1948, which gave a value of 14.1 per cent. She looked and felt well, and the pigmentation of the skin had largely disappeared.

## COMMENT

The treatment of simple toxic diffuse goiter with modern surgical technic is eminently satisfactory. Good results have been reported with high voltage roentgen therapy[4] and more recently with thiouracil and other antithyroid drugs. This report points out that certain severe conditions unsuitable for surgical treatment or some conditions that fail to respond to antithyroid drugs, as well as high voltage roentgen therapy, have been successfully managed (in 16 out of 18 cases) with radioiodine. It is extremely dubious whether any other mode of treatment would have offered such good results in this group of patients. We have also treated 26 patients with uncomplicated toxic diffuse goiter with results similar to those reported by others.[5]

In addition to its therapeutic efficacy, it should be pointed out that radioactive iodine therapy would appear to have several other advantages:

1. The lowest reported mortality rate in thyroid surgery in the postoperative period is 0.5 per cent,[4] but the rate in most institutions is probably higher. There has been no death as a direct result of the therapeutic use of radioiodine.

2. Radioiodine can be administered to the ambulatory patient without loss of time from work. As compared with antithyroid drugs, the patient does not need repeated blood cell counts and daily medication, nor is he subjected to the risk of granulocytopenia. Even with propylthiouracil, reactions are reported in 1.6 per cent of the cases.[6]

3. Although radiation sickness has been reported, this has occurred only with larger doses of $I^{130}$, and we have not observed this untoward reaction in our patients.

4. The cost to the patient of treatment with radioactive iodine is much less than the cost of operation.

5. The administration of radioactive iodine is not followed by such complications as hypoparathyroidism, severe thyroid storms, postoperative pneumonia, shock, granulocytopenia, laryngeal paralysis, cosmetically unsightly scars and emotional strain of a major surgical procedure.

6. So far, evidence points to a decreased incidence of progressive exophthalmos with radioactive iodine therapy as compared with its incidence with surgical treatment.[3]

The disadvantages of radioactive iodine therapy are:

1. The correct dosage of radioactive iodine is not accurately known. As a result, in some cases many months of treatment are necessary before there is a remission. In other cases too much radioiodine has been administered with resulting hypothyroidism. With further experience it should be possible more accurately to gage the dosage so that the number of inadequately treated and overtreated patients will be reduced.

2. There are certain unknown dangers from radiation. Although no complications have as yet been seen in our cases or reported in the literature, the theoretical possibility exists that some dangers may be present.[7]

3. With surgical treatment the histologic changes of the gland can be accurately appraised. The pathologic changes, of course, can only be surmised without removal of the gland.

4. A certain amount of technical skill and apparatus is required to administer $I^{131}$ properly and safely.

5. Radioiodine has been used only since 1941; it is a relatively new form of treatment, and unforeseen difficulties may occur as in any new form of therapy.

## SUMMARY

Radioactive iodine was used in 18 problem cases of severe toxic diffuse goiter (Graves' disease). There were five classifications of complications: (1) congestive heart failure (3 cases), (2) extreme emotional instability or psychosis (3 cases), (3) extreme toxicity (3 cases), (4) recurrence after previous thyroidectomy (8 cases) and (5) thyroid malignancy (1 case).

Of the 18 patients, 16 were brought to a euthyroid state. One died of unknown cause several months after complete remission; 1 patient still had mild toxic symptoms, although greatly improved, at last examination, and in only 1 patient was there frank therapeutic failure.

# MEDICALLY PRESCRIBED EXERCISES FOR NEUROPSYCHIATRIC PATIENTS

## The Veterans Administration Program

A. B. C. KNUDSON, M.D.
AND
JOHN EISELE DAVIS, Sc.D.
Washington, D. C.

Today, as medical progress continues to record advancement in the prevention, diagnosis and cure of disease, psychiatric illness has become the primary medical problem of the nation—indeed, even of the world. Physical medicine as a specialty is so closely associated with psychiatry in the rehabilitation and restoration of mental patients that their objectives are almost synonymous. Physical medicine, like psychiatry, is a social as well as a medical science concerned with the patient's recovery, then his adjustment to family and community and finally his economic independence.[1]

Burlingame[2] has stressed the importance of physical medicine in aiding the psychiatrist in restoring psychiatric patients to society. Hawley[3] pointed out the rehabilitation potentials of psychotic patients. Blain[4] emphasized the importance of activity rehabilitation measures in the restoration of patients with chronic mental illness and in aging patients with mental disorders.

The Physical Medicine Rehabilitation Service in neuropsychiatric hospitals of the Veterans Administration consists of five component sections: physical therapy, occupational therapy, corrective therapy, manual arts therapy and educational therapy (fig. 1). These treatment technics are essential to the total recovery program, and this specialty is a service to the psychiatrist in development of therapeutic objectives for mental patients. The Chief of the Physical Medicine Rehabilitation Service is a qualified physiatrist and, in many neuropsychiatric hospitals, is also certified in the neuropsychiatric field. The same organizational setup is available to the psychiatrist in the neuropsychiatric units of general medical and surgical hospitals.[5]

The role of corrective therapy in the neuropsychiatric hospital will be outlined and some notation made of current progress. The Baruch Committee on Physical Medicine, in its plan for organization of rehabilitation staffs and centers, stated that the

> . . . physical medicine branch should be divided further into three sections: the section on occupational therapy, the section on physical therapy and the section on physical education.[6] The Veterans Administration has accepted this policy and, similar to Army Physical Reconditioning, has organized a section on physical activities designated as Corrective Therapy. Previous to World War II physical exercise was a part of hospital treatment in Veterans Administration Neuropsychiatric Hospitals, but was organized on a purely group, diversional level. With the organization of the Corrective Therapy program in the Veterans Administration by Covalt, these activities for the first time became organized on an individual medically prescribed basis as part of the total therapeutic plan in Physical Medicine Rehabilitation, and as such are coordinated with physical therapy, occupational therapy, and the other sections. This change merits further explanation in that the earlier plan utilized physical exercise as a diversional group program coordinated with, but not an integral part of, the medical service. As Corrective Therapy is now developed in the Veterans Administration, it is directly under the doctor, the physiatrist and the psychiatrist, as a prescribed medical activity to be administered in accordance with the prescription. Rusk, in his Convalescent Army Air Forces program, described this transition, "Exercises by the numbers as given in mass calisthenics during the soldiers' early military training are now replaced by personalized, prescribed activity and reconditioning procedures."

Rusk,[7] Barton[8] and Thorndike,[9] as well as many others, having seen the beneficial results of convalescent activity programs for neuropsychiatric patients, have included this phase as a part of state, civilian and university hospitals and teaching programs.

Attention is called to the developing relationships between the rehabilitation of neurologic and other neuropsychiatric patients. One of the earliest significant accomplishments was the effective rehabilitation of several chronic neurologic patients at the Minneapolis Veterans Administration Hospital, in which corrective therapy made a significant contribution. Brown[10] observed, "Probably of all medical conditions, the chronic neurologic disorders have for years been the most completely neglected." He showed from his study that the success with the individual patient was not directly proportional to the chronicity of the condition, but that patients hospitalized up to twenty years, many of them bed patients, could be rehabilitated and discharged from the hospital.

It is our belief that similar results may be attained in the rehabilitation of psychiatric patients. The patient falling into a passive daily routine of institutional life may easily become chronic. As Blain[11] explained, "Here it has been easier to lie down in the fight. After most therapeutic weapons have been tried, doctors and others become discouraged, not knowing what to turn to next. We have to change the attitude which has been handed down to us from time immemorial that chronic mental patients are essentially hopeless." With greater concentration on the chronic group, reports of a recent month showed that out of 5,500 discharged patients from neuropsychiatric hospitals where we have activity programs, 1,400 were World War I veterans, averaging 54 years of age and averaging more than five years in the hospital. This points to the need for augmented "total push" methods in our neuropsychiatric hospitals.

### PERSONNEL

The present patient load in neuropsychiatric hospitals, the future load based on past experience and the large number of World War II veterans offer one of the greatest challenges in Veterans Administration medicine (fig. 2). On May 4, 1948, there were 53,079 neuropsychiatric patients. It has been estimated that this load would increase to 122,000 by the peak year of 1965. There are about 400 corrective therapists in

[11] Blain, D.: Priorities in Psychiatric Treatment of Veterans, Mil. Surgeon **102**: 85 (Feb.) 1948.

Veterans Administration hospitals selected from 20,000 reconditioning personnel, of which about one fourth are concerned with psychiatric patients. These corrective personnel have a minimum degree of Bachelor of Arts or Bachelor of Science in physical education and have had specialized courses of instruction in psychiatric applications at the Veterans Administration Hospital, Topeka, Kansas, under Dr. Karl Menninger. They are supplemented by volunteer workers. In view of this, we find it advisable to develop our rehabilitation program for mental patients in accordance with the stated priorities outlined by Blain.

### BASIC CONCEPTS IN CORRECTIVE THERAPY

The fundamental concepts underlying the organization and execution of the corrective therapy program may be stated as follows.[12] Exercises are considered to have a distinctive effectiveness in meeting the emotional needs of the patient. The value, however, depends on the ability of the therapist to modify these exercises and to produce activity situations which will attract the patient into improved social adjustment. The major interest is not in the development of exercise per se, but in its integration into a total situation in which the patient is willing to accept a higher level of socialization. In this motivated environment the therapist is able to create most effective interpersonal relationships. The patient's hostility should be met without counterhostility on the part of the therapist. He must attempt to penetrate through activity the patient's mutism, rigidity, apparent obliviousness and other psychiatric symptoms. To accomplish this the therapist must have the competence, achieved through training and experience, to comprehend the significance of different types of symptoms and to realize the requirements of his role as a corrective therapist. The corrective therapist should develop a favorable therapeutic rapport with the patient, thus establishing a usable transference, which will permit progression to higher activity.

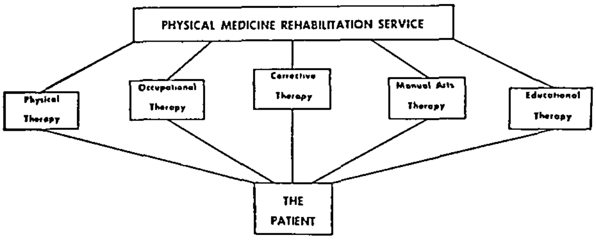

Fig. 1.—Organization of physical medicine rehabilitation service in the hospital.

The corrective therapist must follow no rigid rules of applying activity, but should "individualize" as much as possible. There should be a constant readjustment of activities as the patient progresses. A proper therapist-patient relationship at all stages of activity is important; the therapist always striving to represent the external environment. It is generally agreed that there is no more natural situation in which the individual may express his spontaneous and natural behavior than in exercise, especially a play situation. Here the corrective therapist can help in formulating ideas regarding the patient's behavior patterns and personality trends that resulted in maladjustments prior to the onset of mental illness.

Corrective therapy procedures, as a part of the total treatment plan, have proved helpful in the allaying of anxiety, the easing of rigidity, the lessening of inhibitions, the establishing of good rapport, lessening distractibility, resolving feelings of inferiority and overcoming negativism. Reassurance and desensitization of the ego is favorably influenced by physical participation in competitive and social types of exercise.

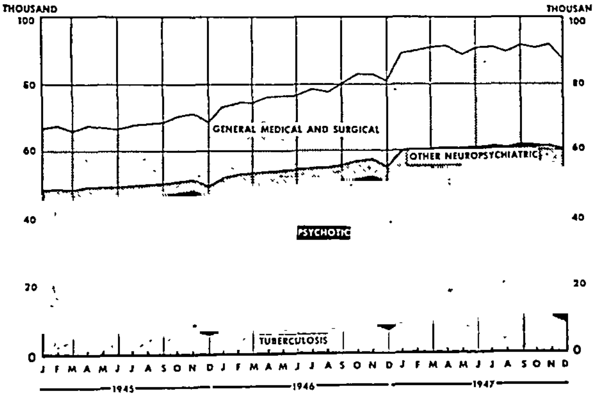

Fig. 2.—Graph of patients remaining in Veterans Administration hospitals, by type of disorder (tabulations made at the end of each month), 1945-1947.

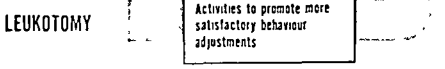
It is frequently instrumental in awakening the will to recovery and in developing cooperation on the part of the patient. It has been noted that the active and often the voluntary element is significantly developed, thus emphasizing the principle that the patient's participation in activity forms a conspicuous contribution, both on physiologic and psychologic lines. Corrective therapy may therefore be considered a valuable adjunct to psychotherapy. It should be emphasized that active exercise is the most commonly used form of corrective therapy as applied to psychiatric patients.

It is considered important to survey and evaluate these situational activities and their various modifications as a dynamic, socialized, individual approach for improvement and possible rehabilitation of mental patients. Present empiricism has been due to a lack of time in a new program for controlled scientific evaluations.



ORAL PSYCHOTHERAPY
AIM
Utilization of meaningful physical activities as part of group and individual psychotherapy.
SHOCK THERAPY
AIM
Activities as a psychological follow up as the patient becomes more accessible after shock
LEUKOTOMY
AIM
Activities to promote more satisfactory behaviour adjustments
IMPROVED HOSPITAL ADJUSTMENT
TRIAL VISIT
DISCHARGE

Fig. 3.—Corrective therapy individualized and medically prescribed as an adjunct to the types of therapy shown.

In the gradual evolution of this program it has been determined that socialization is no longer a sufficiently specific therapeutic aim. Daily experience is producing motivated situations which are being modified to meet the more exact psychiatric needs of the patient. For example, it is now evident that activities may be adapted to produce higher levels of aggression, to develop a natural release of aggressive feeling, to realize such therapeutic aims as release of guilt feelings, and to attain narcissistic gratification. There is a definite trend toward more intensive specialization in this application of corrective exercise for the mental patient. This leads to a consideration of the possibility of modifying activities to meet the distinctive physical and personality needs of the patient and to draw out his social potentials for eventual resocialization. It is extremely important to begin corrective therapy as early as possible for achievement of the best results; this insures an adequate outlet for the patient's interest, time and energy; it satisfactorily substitutes activities for the patient's inactivity, and thus initiates constructive efforts toward ultimate rehabilitation.

---

[12] Davis, J. E.: Exercises in the Medical Rehabilitation of Mental Patients, Occup. Therapy 26: 225 (Aug.) 1947.

Provision is made for the employment of naturally motivated activities in the form of exercise and play for the purpose of carrying out medically prescribed treatment. Major emphasis is placed on attracting the patient into activity and sustaining his interest in continued participation. Multiple grades and types of exercise are used. The corrective therapist as has been indicated is part of the total therapeutic team working under the supervision and direction of the psychiatrist and physiatrist, making ward rounds, reporting to them and regularly attending staff conferences. Activities are classified as to form, socialization and also application to disease entities when this is practicable within the range of our increasing experience.

### CLASSIFICATION OF EXERCISES AS TO FORM

1. *Correctives.*—Highly organized to remedy a specific condition.

2. *Reconditioning Exercises.*—For increase of strength and endurance. For psychiatric patients of all categories who may need such physical upbuilding.

3. *Educational Physical Exercises.*—To teach motor skills. For example, teaching the distractible schizophrenic patient to improve his golf game with the idea of stabilizing conduct through improved emotional control which comes from increased bodily control.

4. *Informal Activities.*—Especially conditioned for specific physical and mental dysfunction. For example, table tennis for partly paralyzed arm in which the exercises become motivated through play.

5. *Social Activities.*—In which the stress is placed on the cooperative rather than the competitive aspect of play, playing with rather than against people.

6. *Postural Exercises.*

7. *Swimming.*—For negativism, hysteria, sedation of hyperactive patients and stimulation for depressed types requiring reactivation.

8. *Specialized Preoperative and Postoperative Exercise.*—In connection with leukotomy, insulin and electric shock.

### CLASSIFICATION OF ACTIVITIES FOR SOCIALIZATION

1. Individual solitary activity—for certain schizophrenic patients who will not play in a group but must be inducted initially on an individual basis, such as solitary bowling.

2. Selective small group activities for patients who find favorable psychotherapeutic transference in small groups, such as badminton and code ball.

3. No body contact: volleyball, tennis, bowling, golf and calisthenics—for patients who suffer psychic trauma from physical contact.

4. Body contact activities: wrestling, boxing, football, tug of war—for patients who because of preformed skills and innate interest in these activities are favorably conditioned to accept physical contact.

### GENERAL FUNCTION OF CORRECTIVE THERAPY

The general functions of corrective therapy indicated by the role of corrective therapy in modern treatment o[illegible] patients is shown in figure 3. I[illegible] the patient's reaction are made by the corrective therapist as an aid to continued treatment and diagnosis. This physical exercise observation report (figs. 4 and 5; parts I and II of observational report) is intended as a guide for the organization of pertinent information which the therapist is able to discover in the exercise situation. Special training courses have given our personnel insight into the distinctive psychotherapeutic problems involved, particularly the transference between therapist and patient. Personnel have been chosen with major stress on selective personality factors which have been tabulated in a battery of psychologic tests enabling the Veterans Administration to utilize these most effective components in future placement.

*Functions of Corrective Therapy*

1. To give instructions to neuropsychiatric patients in activities, individually prescribed by the physician, based on the specific needs and abilities of the patient.

2. To provide adequate treatment for neurologic patients by the use of active exercise to reeducate the neuromuscular system to the maximum.

3. To administer a program of scientifically prescribed exercise for patients on the general medical and surgical service.

*Classification of Activities for Application to Disease Entities*

| Psychiatric Condition | Aim of Activity | Type of Activity |
|---|---|---|
| Transient personality<br>Reactions to acute or special stress | To aid in the alleviation of the effects of situational stress | Any type of exercise or play of an interesting nature suited to the patient's physical tolerance and favorable to the environmental readjustments desired |
| Psychoses<br>Functional | To aid the patient's return to reality | Activities of a socially infectious nature. All types of simple and complex exercises and games based on severity of symptoms, external precipitating stress, premorbid personality, predisposition and inherent skills |
| Psychoneuroses | To aid in the relief of anxiety | Exercises and play activities involving gross movement, prescribed with special reference to patient's physical tolerance and potentials for the externalization of anxiety into activity |
| Psychoses<br>Organic<br>Syndrome of Deficit (Meyer) | To provide interesting and socially constructive activities within the physical and mental capacity of the patient | Exercises generally of a simple noncomplex nature; possible confusion, reduction of intellectual capacity, delirious trends, moral, ethical and esthetic aberrations and cover-up mechanisms taken into account |

Physical exercises providing a psychologic follow-up to electric shock therapy are differentiated for preshock and postshock categories, are administered daily for approximately one hour and are started about eighteen hours prior to shock. Patients are divided into three groups for swimming activities as follows:

1. Hyperactive and aggressive patients engage in fast exercises, as water volleyball, water goal high.

2. Less active patients take part in simple swimming skills and water coordination exercises.

3. Regressed and depressive types participate in light calisthenic drills and coordination exercises.

Postshock exercises begin approximately five and one-half hours after shock treatment, patients being segregated in the same manner as for preshock.

Experience has developed the following general objectives: (1) relief of body soreness, (2) reawakening of confidence and agression, (3) sedation and stimulation through swimming, (4) development of coordination, muscle tone and strength and (5) fundamental skills..

RESULTS

Corrective therapy is part of the well rounded program of physical medicine rehabilitation for patients who have undergone leukotomy. Reports received, covering several hundred patients treated, give an important status to this adjunct therapy. Patients with most unfavorable prognosis may participate at first in childike imitative manner, later becoming more animated, spontaneous and interested. Figure 6 is a chart of a typical case. This includes a personality record paralleling an activity record, the latter showing elemental, individual and group levels. Postoperative therapeutic methods attack such manifestations as lack of spontaneity, carelessness, indiscretion of speech, indifference for the future and distractibility. These patients are attracted to individually prescribed exercises, and, in the words of a chief of physical medicine, "The flattened expression may leave the face after a month and improvement through corrective therapy carries over to other activities." The patient who has undergone leukotomy is seen in the Corrective Therapy Department about the fourth postoperative day. Two or three weeks usually pass before interest and rational effort are elicited, during which time the patient may become motionless and seclusive or may participate in some elemental activity, as playing catch with almost any type of ball. The patients usually go through a period of aggression during the improvement phase, during which they are able to find helpful outlets through corrective exercise. Patients become naturally divided into two groups, fast and slow, the former comprising those whose operation was performed as long as a year previously, while the slow group comprises those operated on more recently.

The general results of leukotomy combined with postoperative psychiatric and physiatric therapy indicate that about one third of the patients are able to return home, one third improve in the hospital and one third show no improvement or become worse.

An exploratory training technic has been developed for stuporous and mute catatonic patients. Elemental assistive and resistive exercises are combined with educational retraining methods to parallel mental reactivation with physical stimulation. Psychologic exercises are added to assist the patient to regain recognition of objects as to shape, size, design and utilitarian value. A most effective transference is shown by the decrease in explosive behavior generally associated with these cases. Reports indicate considerable promise for this procedure which attacks these difficult and inaccessible types through early activity.

Other exploratory methods are arranged with occupational therapy through which regressed patients whose interest span is limited are activated by means of exercises and referred back to the occupational or manual arts therapy departments for reassignment.

A reintegrative research program is being carried out in one of the large Veterans Administration neuropsychiatric hospitals to determine whether an intensive regimen of varied activity can reclaim patients who have not responded to either psychotherapy or drastic shock and to determine whether corrective procedures can prevent further regression.

Fig. 5.—Observational report, part 2.

There is a definite trend in all of the Veterans Administration neuropsychiatric hospitals to lay greater stress on the value of motivated exercise situations as adjuncts to psychotherapy. Total push programs utilize all possible facilities and types of therapy executed by the entire therapeutic team.

Corrective therapy offers these discussion groups strenuous but enjoyable physical activity, which acts as a cohesive and binding influence on its patient-members. Proficiency charts with suggested activities are kept. Group games, both competitive and noncompetitive, are provided for the purpose of creating a strengthened attitude of sociability, made possible as the patients play and work together in a unit. This effort of understanding one another in a modifiable and relaxing atmosphere helps to overcome withdrawal tendencies and has developed helpful transference among the members of the group. Both corrective therapists and psychotherapists are impressed with the possibilities of utilizing such highly motivated situations in the promotion of a total treatment program.

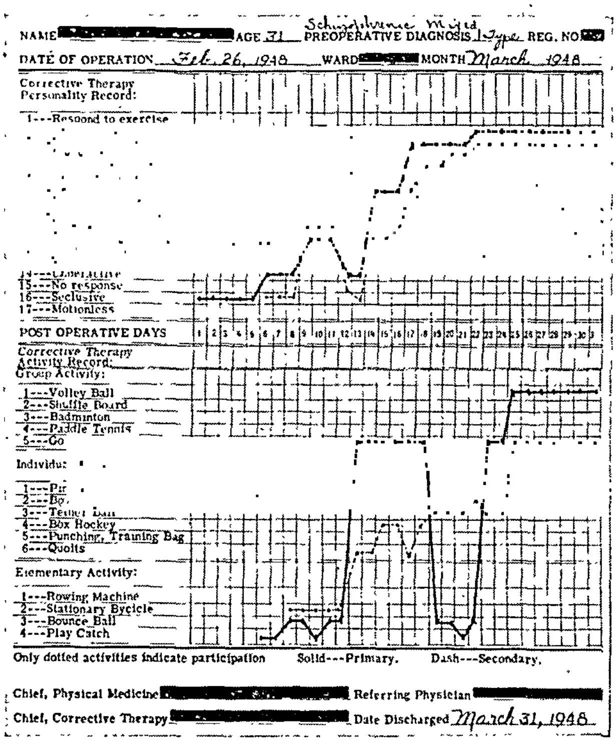

Fig. 6.—Prefrontal leukotomy reaction chart.

Factual data and reports coming from hospitals that have sections of corrective therapy contain numerous examples of the externalization through medically prescribed activities of hostile combativeness and other behavior aberrations, permitting the patient to give expression to these drives in a more socially acceptable way and thereby lessening need for active restraint. One hospital reports the results of a medically prescribed swimming program as follows: The average number of restraints was reduced by 65 per cent; serious disturbances were reduced by 75 per cent, and the average amount of additional sedation was remarkably reduced, with one less attendant needed on the ward during the day. An exercise program on the service for acute disturbances of a 2,000 bed hospital effected a reduction of wet packs by 1,233 over a period of six months. Another large hospital reports a decline of tub treatments from 295 to 78 and packs from 364 to 325 over a period of three months. Figure 7 shows results of swimming in minimizing the need for restraint.

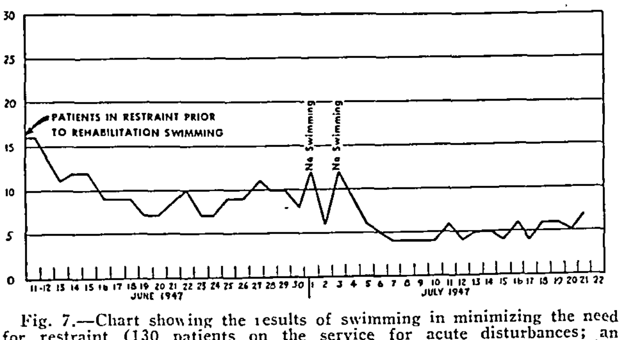

Fig. 7.—Chart showing the results of swimming in minimizing the need for restraint (130 patients on the service for acute disturbances; an average of 20 of the most acutely disturbed patients engage in swimming twice daily).

Stimulation of interest in exercise is stressed for aged patients, for training in activities essential to daily living and establishing effective health habits (fig. 8). Light exercises are selected with coordination as a primary aim. Preference is given to such simplified and easily motivated activities as modified hiking, swimming, shuffleboard and croquet. Exercises are given to prevent or correct postural defects. The therapeutic aim is to prevent deconditioning, to enable the patient to retain the vegetative reflexes and to care for daily needs of dressing and self feeding.

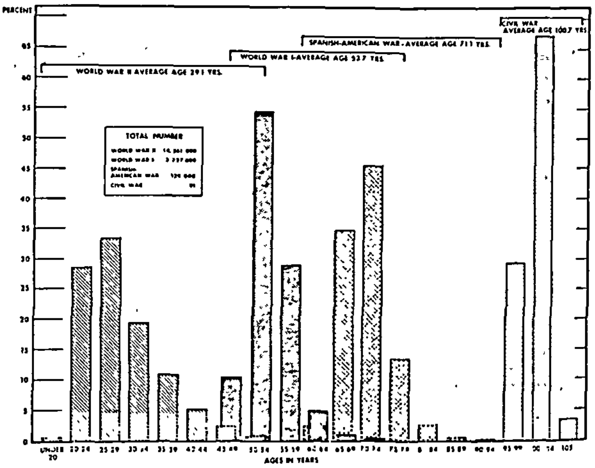

Fig. 8.—Chart showing age of living veterans as of June 30, 1947.

Research studies are laying the basis for programs and technics which will take into account the skill level along with physical tolerance and psychologic potentials which will enable the patients to find solid satisfaction from activity. Psychologic observations point to the significant element of regression rather than chronologic age as a major factor requiring careful study in an over-all study of geriatrics.

## SUMMARY

Corrective therapy is a positive therapeutic agent which has been developed as a part of physical medicine rehabilitation in the Veterans Administration. It is too soon to evaluate definitely the net results of many of the technics in corrective therapy, but their value has already been proved in many psychiatric illnesses.

Just as physiologic effects of exercise may aid in reestablishing former patterns of motion in neurologic conditions resulting from lesions of the central nervous system, so in psychiatric disease new behavior patterns are developed by corrective methods which can be guided by the psychiatrist and the physiatrist advantageously toward normal behavior and eventual recovery.

In physical medicine it may be several years before the exactness of dosage of various procedures will be definitely established as compared with pharmaceutic dosage. Likewise, in corrective therapy the surface of the possibilities in this field have barely been scratched. Much remains to be done in the proper evaluation, observation and study of various methods so as to derive the optimal type, frequency and duration of dosage for various mental conditions.

Corrective therapy in the Veterans Administration has stimulated a renaissance of interest and a concerted attack in this field throughout neuropsychiatric hospitals on the problem of the best methods of treatment of mental illness with prescribed activity. Psychiatrists are viewing progress along these lines with interest and anticipation.

### CONCLUSIONS

1. Corrective therapy has proved its usefulness in the psychiatric field through its application to mental illness as a dynamic adjunct to psychotherapy and as a component section of total rehabilitation in coordination with other rehabilitation sections of the physical medicine rehabilitation service.
2. Corrective therapy has been of definite therapeutic value in its specialized application in catatonic patients and for postshock and postleukotomy conditions.
3. Corrective therapy offers new avenues of approach to the rehabilitation of aged patients with chronic mental illness.
4. The further practical application of the principles of corrective therapy, based on observation, research and evaluation of progress, should lead to new and even more beneficial results.

---

## Council on Physical Medicine and Rehabilitation

### REPORT OF THE COUNCIL

*The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.*

*The Council wishes to express its appreciation for the valuable assistance rendered in the preparation of this report by Drs. Gordon Berry, Hallowell Davis, Kenneth Day, E. P. Fowler, Isaac H. Jones, Dean Lierle, Moses H. Lurie, Douglas Macfarlan, C. Stewart Nash and Paul E. Sabine.*

HOWARD A. CARTER, *Secretary.*

### MINIMUM REQUIREMENTS FOR ACCEPTABLE PURE TONE AUDIOMETERS

An audiometer is a device used to measure the sensitivity of hearing. The particular type of audiometer with which this specification is concerned is the pure tone audiometer designed for general diagnostic use with individual subjects. This specification has been prepared with the objective that the measurements obtained on any audiometer shall truly represent a comparison of a person's auditory threshold at prescribed frequencies with the corresponding normal thresholds. A hearing test of a given person on all audiometers designed in accordance with the standards should yield substantially the same results when performed under similar conditions of ambient noise.

The normal threshold of hearing at a given frequency is the modal value of the minimum sound pressure which at that frequency produces a sensation of pitch in a large number of normal ears of persons in the age group from 18 to 30 years, inclusive. The threshold of hearing is measured by presenting tones of successively greater or less intensity to a listener.

#### 1. GENERAL REQUIREMENTS

(*a*) The audiometer shall be an electroacoustic generator, with associated air and bone conduction receivers, which provides pure tones of selected frequencies covering a considerable portion of the auditory range. The frequency and intensity shall be controllable.

(*b*) The audiometer shall operate by electrical power from one or more of the following sources: battery power supply, direct current at line voltage of 117 volts and alternating current at 60 cycles per second and 117 volts. Tests for compliance with the requirements of sections 2 and 4 shall be made at line voltages of 110 and 125 volts or at the extremes of the usable range of battery voltages recommended by the manufacturer. Tests for compliance with the requirement of sections 3, 5, 6, 7 and 8 shall be made at a line voltage of 117 volts or at the battery voltage recommended as operating voltage by the manufacturer.

(*c*) The audiometer shall have a nameplate giving the manufacturer's name, the serial number, the voltage and frequency (or frequencies) of the power supply and the power consumed by the audiometer.

#### 2. FREQUENCIES

(*a*) The audiometer shall produce at least the following definitely identified frequencies: 125, 250, 500, 1,000, 2,000 and 4,000 cycles per second for both air and bone conduction measurements, and also 8,000 cycles per second for air conduction measurements. Dials shall be marked so that frequencies in cycles per second can be easily read.

(*b*) Each frequency generated by the audiometer shall have a value within ±5.0 per cent of the corresponding frequency reading.

#### 3. INTENSITY INTERVAL AND INTENSITY RANGES FOR AIR CONDUCTION

(*a*) The readings of the intensity dial or scale shall be hearing-loss readings, i. e., when the intensity dial is set at zero the intensity of the tone produced shall be at the normal threshold of hearing for that frequency as defined in section 4*a*, and other readings shall indicate the ratio, expressed in decibels, of the intensity of the test tone to the corresponding normal threshold of hearing.

(*b*) Hearing-loss readings shall extend from 10 decibels below threshold by intervals of 5 decibels or less up to at least the values given in table 1.

(*c*) At each of the foregoing frequencies the measured difference (in decibels) of the intensity levels corresponding to any two graduations of the intensity dial shall agree with the indicated difference in hearing-loss readings within 1.5 decibels. Thus for a 5 decibel interval on the intensity dial, the measured difference in intensity levels shall not be less than 3.5 decibels or more than 6.5 decibels. The difference in the intensity levels shall be determined by measurement of the voltage levels at the input of the receiver with the receiver coupled to the National Bureau of Standards coupler 9-A or its acoustic equivalent.[1]

TABLE 1.—*Value for Hearing-Loss Readings*

| Frequency Reading in Cycles per Second | Hearing-Loss Readings in Decibels Above Normal Threshold |
|---|---|
| 125 | 65 |
| 250 | 80 |
| 500 | 85 |
| 1,000 | 95 |
| 2,000 | 95 |
| 4,000 | 90 |
| 8,000 | 75 |

---

[1] The National Bureau of Standards Coupler 9-A has been used by audiometer manufacturers and the National Bureau of Standards as a standard coupler for many years. Its volume is approximately 6 cc. Recently the American Standards Association, Inc., has prepared American Standard Z24.9/186, in which a coupler designated American Standards Association Type 1 is recommended. Adaptation of the American Standards Association Type 1 coupler, or of any other coupler, to the different earphones supplied by audiometer manufacturers involves research, and consequently the issuance of this standard would be delayed by one or more years, if any coupler other than no. 9-A were to be incorporated into the standard. The American Standards Association, Inc., plans to rewrite American Standard Z24.9/186 as soon as the basic research has been completed. The industry and the requirements of the Council on Physical Medicine and Rehabilitation will then change gradually from the National Bureau of Standards coupler 9-A to a standard coupler approved by the American Standards Association. The phrase "or its acoustical equivalent" in the present requirements is intended to include any standard coupler approved by the American Standards Association as a substitute for or to replace the National Bureau of Standards coupler 9-A.

### 4. SOUND-PRESSURE OUTPUT OF THE AIR CONDUCTION RECEIVER

(*a*) *The sound pressure produced by the air conduction* receiver at each hearing-loss reading shall not differ from the indicated value, as referred to normal threshold, by more than 4 decibels at the indicated frequencies of 125, 250, 500, 1,000 and 2,000 or by more than 5.0 decibels at 4,000 and 8,000 cycles per second. Measurements of sound-pressure output shall be made with the receiver coupled to the National Bureau of Standards coupler 9-A or its acoustic equivalent. The sound pressures in coupler 9-A corresponding to normal threshold have been determined by the National Bureau of Standards for several types of receivers. For other types the methods of comparison advised by the National Bureau of Standards or specified by the American Standards Association, Inc., shall be employed. For Western Electric Type 705-A receiver the threshold pressures, determined by loudness balancing with the receivers used in the National Health Survey Hearing Study, are given in table 2.

TABLE 2.—*Threshold Pressures for Western Electric Type 705-A Receiver*

| Frequency in Cycles per Second | Root-Mean-Square Sound Pressure in Decibels Above 1 Dyne/Cm.$^2$ |
|---|---|
| 125 | —19.5 |
| 250 | —34.4 |
| 500 | —49.2 |
| 1,000 | —57.3 |
| 2,000 | —57.0 |
| 4,000 | —58.9 |
| 8,000 | —53.1 |

(*b*) The sound-pressure output of an audiometer shall be measured directly at the hearing-loss settings of 60 decibels. It shall be obtained at all other intensity readings by combination of the pressures measured at 60 decibels with the results of the measurements of hearing-loss interval as specified in section 3.

### 5. PURITY OF TEST TONES OF THE AIR CONDUCTION RECEIVER

The sound pressure of the fundamental signal shall be at least 25 decibels above that of any harmonic when measured with the receiver coupled to the National Bureau of Standards coupler 9-A or its acoustic equivalent. The harmonics shall be measured at the frequencies and hearing-loss settings listed in section 3*b*, even though the manufacturer may provide a maximum intensity higher than is specified in that section.

### 6. NOISE IN THE AIR-CONDUCTION RECEIVER

The root-mean-square weighted sound pressure due to all frequencies except the signal frequency and its harmonics shall be either less than 1.0 by $10^{-3}$ *dyne per square centimeter or at* least 60 decibels below the sound pressure due to the signal frequency and its harmonics at all specifically designated frequencies and hearing-loss dial settings. The measurement of noise shall be made with the oscillator of the audiometer inoperative, but with the remainder of the circuit in normal operating condition. The other conditions of this measurement and the relative weights employed in the calculation shall be those specified by the American Standards Association, Inc., for this purpose (American Standard Z24.9/186).

### 7. TONE INTERRUPTER

An audiometer shall be equipped with a device for turning the tone on and off without introducing an objectionable click (i. e., transient extraneous frequencies, audible to a normal ear) in the receiver. In addition, it is recommended that the time required for the rise and decay of the test tone be within 0.1 to 0.5 second to reach ±1 decibel of the required sound pressure.

### 8. THE BONE CONDUCTION RECEIVER

Audiometers shall be supplied with bone conduction receivers for measuring the threshold of hearing for bone-conducted sound.

(*a*) A suggested procedure for establishing the normal threshold of hearing for bone-conducted sound as measured by a particular audiometer is as follows: Determine at each frequency the intensity level, as measured by the hearing-loss setting of the audiometer, which can just be heard when the bone conduction receiver is pressed firmly against the mastoid just back of the ear of each of 6 subjects with hearing losses at the frequencies employed of not more than 10 decibels by air conduction. The mean of the six measurements at any frequency is taken as the normal threshold for bone-conducted sound of that frequency. This average will be the zero setting of the particular audiometer for bone-conducted sound of that frequency. All measurements specified in this section are to be made in a room free from extraneous sound of sufficient intensity to vitiate the measurements. Acceptance tests on this requirement may follow the same procedure.

(*b*) The bone conduction receiver shall not radiate sound to such an extent that the sound reaching the tympanum through the auditory meatus might influence the validity of the bone conduction measurement. As judged by an observer with normal hearing, the sound received at the ear by air radiation from the bone conductor shall have a sensation level at least 5 decibels below the level which the receiver generates by bone conduction when in contact with the head.

This test shall be performed by determining the bone conduction threshold in the usual way, and then, with the bone conductor held in approximately the same position as in the threshold measurement, but with the driver element or contact area of the receiver resting on the soft flesh at the end of the operator's finger and with closure comparable to that provided by contact with the mastoid, the threshold at which any auditory sensation is perceived shall be noted. Care must be taken that no direct contact be made between the finger and skull. The threshold of auditory sensation shall be at least 5 decibels above the direct bone conduction threshold. A jury of at least 6 persons with hearing losses for air-borne sound not greater than 10 decibels at the frequencies employed shall perform the test and the mean of their results taken. The above test is not required at frequencies above 2,000 cycles per second.

### 9. AUDIOGRAM BLANKS

If the manufacturer supplies with his instrument blanks for plotting measured hearing losses, these blanks shall comply with the following specifications: The blank shall be ruled with rectangular coordinates, with frequencies in cycles per second on a logarithmic scale as the abscissas and hearing loss in decibels on a linear scale as the ordinates. Frequencies shall be shown by vertical lines equally spaced at octave intervals. (For an instrument that produces test tones at intermediate frequencies, vertical lines to correspond to these frequencies should appear at the proper fractional parts of the octave intervals.)

Normal hearing for both air-borne and bone-conducted sounds shall be indicated by a single horizontal line marked 0 (zero), near the top of the blank. "Hearing loss in decibels" shall be indicated by horizontal lines, equally spaced at 10 decibel intervals and numbered downward from the 0 line. One octave on the frequency scale shall be the same distance as 20 decibels on the hearing loss scale.

### 10. SHOCK HAZARD

Audiometers shall be free from electric shock hazard. A shock hazard shall be considered to exist at an exposed live part if the open circuit potential is more than 25 volts and the current with a 1,500 ohm load is more than 5 milliamperes.

### 11. GUARANTIES

The manufacturer shall make to the purchasers the following guaranties: (*a*) Any defect other than those due to accident or damage from improper use that may appear within a period of one year from date of purchase will be corrected and the instrument recalibrated at no cost to the purchaser except for transportation charges; replaceable parts which may deteriorate with use, such as vacuum tubes, shall, by agreement, be supplied at reasonable cost.

(*b*) The maker will provide adequate instructions for the proper care and upkeep of his products and will encourage the purchaser to send his audiometer at reasonable intervals to the factory or to a qualified distributor for check as to performance and needed servicing at a reasonable cost.

### 12. MARKETING AND ADVERTISING

Rules of the Council on Physical Medicine and Rehabilitation shall be adhered to by manufacturers of acceptable audiometers.

*The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.*

AUSTIN SMITH, M.D., *Secretary.*

**SODIUM SULFATE.—U. S. P.—$Na_2SO_4.10H_2O$.**

For description and standards see the U. S. Pharmacopeia under Sodium Sulfate.

*Actions and Uses.*—Sodium sulfate administered orally in solution acts as a saline cathartic, but it is considered more disagreeable and less active than magnesium sulfate for this purpose. Sodium sulfate, however, possesses useful diuretic properties that are less well known clinically. As a diuretic it is administered intravenously in the form of an isotonic (4%) solution in distilled water. The resulting diuresis is believed to be due to the impermeability of the tubule cells to the salt, which therefore remains in the tubules and diminishes the absorption of water by its osmotic action. In animal experiments, sodium sulfate was shown to be the most effective of the salts commonly used for this purpose. Following intravenous injection, sodium sulfate is excreted almost completely in the urine with little or no retention of the sodium ion. It is essentially nontoxic when administered in this manner.

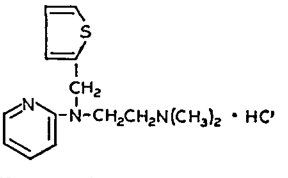
Isotonic solution of sodium sulfate has been found to be effective as a diuretic agent in the treatment of oliguria or anuria secondary to the crush syndrome, burns, transfusion reactions, toxic hemolysis and obstructive lesions of the genitourinary tract. It should be emphasized that mechanical obstruction to the urinary tract should be corrected before attempting to induce diuresis. The solution may also be tried in the treatment of sulfonamide anuria.

*Dosage.*—In adults the dosage ranges from 1 to 3 liters per day, administered intravenously. The volume and frequency of the individual dose are dependent on the condition of the patient and the response to treatment. No data are available concerning its use in infants and children. The rate of administration, based on animal studies, ranges from 500 cc. to 1,000 cc. per hour, but in man this may be more rapid than necessary. Too rapid injection with overloading of the cardiovascular system should be avoided.

DON BAXTER, INC., GLENDALE, CALIF.

**Solution Isotonic Sodium Sulfate:** 1,000 cc. Vacoliter containers. A solution of sodium sulfate 4 per cent in sterile distilled water.

**METHAPYRILENE HYDROCHLORIDE.—"Thenylene Hydrochloride" (Abbott).**—N,N-dimethyl-N′-(α-pyridyl)-N′-(α-thenyl) ethylenediamine hydrochloride.—$C_{14}H_{19}N_3S \cdot HCl$.—M. W. 297.84.—The structural formula for methapyrilene hydrochloride may be represented as follows:



*Actions and Uses.*—Methapyrilene hydrochloride produces effects similar to those of other histamine-antagonizing agents. Methapyrilene hydrochloride has a moderate therapeutic efficacy and its sedative action is about equal to that of tripelennamine hydrochloride. There is a moderate tendency to gastrointestinal irritation.

*Dosage.*—The average adult dose is 50 to 100 mg. As with other antihistaminics, the dose should be the smallest which will relieve symptoms.

*Tests and Standards.*—

Methapyrilene hydrochloride occurs as a white, crystalline powder having a faint odor. It melts between 159 and 162 C. It is very soluble in water, freely soluble in alcohol and chloroform, and very slightly soluble in ether and benzene. The free base is obtained as an oil upon the addition of a 5 per cent sodium hydroxide solution to an aqueous solution of methapyrilene hydrochloride. A 5 per cent aqueous solution of methapyrilene hydrochloride has a pH between 5.9 and 6.4.

Dissolve about 25 mg. of methapyrilene hydrochloride in 5 cc. of water. Add a few drops of nitric acid, followed by 1 cc. of silver nitrate T.S.: a white precipitate of silver chloride is obtained. Add about 0.1 Gm. of methapyrilene hydrochloride to 2 cc. of sulfuric acid: an orange-red solution is obtained, which becomes reddish brown (*distinction from pyribenzamine hydrochloride*).

Dissolve about 0.2 Gm. of methapyrilene hydrochloride in 5 cc. of alcohol and add 5 cc. of a saturated solution of picric acid in alcohol. Bring the mixture to boiling and then allow to cool: a yellow crystalline methapyrilene dipicrate is obtained.

Add 3 drops of a saturated aqueous solution of Reinecke's salt to 2 cc. of a 1 per cent aqueous solution of methapyrilene hydrochloride: a pink precipitate is formed.

Dry about 1 Gm. of methapyrilene hydrochloride, accurately weighed, at 100 C. for 4 hours: the loss in weight does not exceed 0.5 per cent.

Char about 0.2 Gm. of methapyrilene hydrochloride, accurately weighed, over a low flame. Cool, then add 1 cc. of sulfuric acid and continue ignition until no carbon remains: the residue should not exceed 0.3 per cent.

Transfer about 0.5 Gm. of dry methapyrilene hydrochloride, accurately weighed, to a 100 cc. volumetric flask. Add 50 cc. of distilled water, and 3 cc. of nitric acid. Mix thoroughly, add exactly 25 cc. of 0.1 *N* silver nitrate and fill to the mark with distilled water. Shake the mixture vigorously and allow the silver chloride to settle out. Transfer exactly 50 cc. of the clear, supernatant liquid into a flask and titrate the excess silver nitrate with 0.1 *N* ammonium thiocyanate, using ferric ammonium sulfate T.S. as an indicator. Each cc. of 0.1 *N* silver nitrate is equivalent to 0.003647 Gm. of hydrogen chloride: the amount of hydrogen chloride found is not less than 12.1 nor more than 12.4 per cent.

Transfer 0.1 Gm. of methapyrilene hydrochloride, accurately weighed, to a 100 cc. volumetric flask and dilute to the mark with ethanol. Mix thoroughly and transfer 10 cc. of the solution to another 100 cc. volumetric flask. Dilute to 100 cc. with ethanol; mix well and transfer 10 cc. of the solution to a third 100 cc. volumetric flask and dilute to 100 cc. The final solution (0.001 per cent) exhibits ultraviolet absorption maxima at 2400 ($E^{1\%}_{1cm.} = 623 \pm 6$) and 3050 Å, and a minimum at 2740 Å.

Transfer about 0.2 Gm. of dry methapyrilene hydrochloride, accurately weighed, to a separatory funnel. Add 10 cc. of water, 5 cc. of 0.5 *N* sodium hydroxide and extract with six 20 cc. portions of ether. Collect the ether extract in a separatory funnel and wash with two 5 cc. portions of water. Extract the wash water with 10 cc. of ether and add this ether to the combined ether extracts. Treat the combined ether extracts with 20 cc. of 0.05 *N* hydrochloric acid, accurately measured, and then successively with 10 cc. and 5 cc. of water. Combine the acid and water extracts, heat gently until the ether is removed and titrate the excess acid with 0.02 *N* sodium hydroxide, using a 0.1 per cent alcoholic solution of aurin as an indicator. Each cc. of 0.02 *N* hydrochloric acid is equivalent to 0.005227 Gm. of methapyrilene base. Methapyrilene hydrochloride contains not less than 87.0 nor more than 88.5 per cent of methapyrilene base.

METHAPYRILENE HYDROCHLORIDE CAPSULES AND TABLETS: Tablets and capsules of methapyrilene hydrochloride respond to the identification tests and assays described in the monograph on Methapyrilene Hydrochloride. They contain not less than 95 nor more than 105 per cent of the claimed amount of methapyrilene hydrochloride.

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

**Tablets Thenylene Hydrochloride:** 25 mg., 50 mg. and 0.1 Gm.

**AMINOPHYLLINE-U. S. P.** (See New and Nonofficial Remedies 1948, p. 325).

The following dosage form has been accepted:

THE SMITH-DORSEY COMPANY, LINCOLN, NEB.

**Suppositories Aminophylline:** 0.25 Gm.

**DIENESTROL** (See New and Nonofficial Remedies 1948, p. 377).

The following dosage forms have been accepted:

THE CENTRAL PHARMACAL CO., SEYMOUR, IND.

**Suspension Restrol:** 5 mg. per cc., 10 cc. vials. Preserved with chlorobutanol 0.5 per cent.

**Tablets Restrol:** 0.1 and 0.5 mg.

**METHYLTESTOSTERONE-U. S. P.** (See New and Nonofficial Remedies 1948, p. 410).

The following dosage form has been accepted:

RARE CHEMICALS, INC., HARRISON, N. J.

**Tablets Methyltestosterone:** 25 mg.

**OLEOVITAMIN A-U. S. P.** (See New and Nonofficial Remedies 1948, p. 544).

The following dosage form has been accepted:

BREWER & COMPANY, INC., WORCESTER 4, MASS.

**Gel-ets Oleovitamin A:** Each capsule contains 25,000 U. S. P. units of vitamin A.

**SULFAMERAZINE-U. S. P.** (See New and Nonofficial Remedies 1948, p. 134).

The following dosage form has been accepted:

BREWER & COMPANY, INC., WORCESTER 4, MASS.

**Tablets Sulfamerazine:** 0.5 Gm.

## SIR WILLIAM OSLER—CENTENARY ANNIVERSARY

The greatness of William Osler as a physician was a reflection of his broad approach to medicine and to life. He was outstanding in clinical and scientific medicine, but his greatness resided in his recognition of the importance of the Art of Medicine, which was exemplified in its highest form in contacts with patients and colleagues. Kindliness, a warm personal interest and an all-pervading recognition of the value of the individual were characteristic of Osler in his social and professional life. In "Aequanimitas" Osler expressed his personal belief in the qualities of mind and soul that enable a man to rise superior to the trials of life and meet difficulty, success and sorrow with serenity. The "Principles and Practice of Medicine," written in masterful English prose, was promptly recognized as a masterpiece. Through accuracy of clinical perception coupled with lucidity of expression, his inspiration permeated clinical medical practice. This textbook and its many successive editions tremendously influenced several generations of medical thinking in the English speaking world.

The Editorial Advisory Board of the *Archives of Internal Medicine* dedicated its July issue as the "Osler Memorial Number." Contributors to this issue, most of whom knew Osler well, were closely associated with him in the several phases of his career in this country and abroad. Osler's approach to life and his ability as a clinician, a teacher and a leader of men are well and fully presented. His tremendous influence on medical thinking is described in his accomplishments in Canada, in Philadelphia, at Johns Hopkins and at Oxford. Comments of these men who knew Osler best are replete with the sincerest expressions of warm friendliness and respect. The late Fielding Garrison wrote of Osler, "Every gift of the gods was his—he is one of nature's chosen. It is almost thirty years since he died, and his eminence as a teacher and physician has not waned, indeed the years have added to his glory. No one has in any way taken his place as the young physician's friend and as the world's best doctor."

For these and other qualities on this hundredth anniversary of his birth, Dr. William Osler must be reverently remembered as a great physician, an inspiring teacher and a friend of man.

## ENHANCED PENETRATION OF MUCOUS MEMBRANES

In 1928 Duran-Reynals[1] of the Rockefeller Institute described the presence in testicular extract of a factor which facilitates the spread of vaccine virus in the skin of rabbits. Ten years later Chain and Duthie[2] of Oxford University identified this "spreading factor" as a mucolytic enzyme (hyaluronidase), capable of depolymerizing and thus decreasing the viscosity of the intracellular mucin-like substance in rabbit skin. Hyaluronidase increased the interstitial spread of such diverse substances as india ink, rabies virus, methemoglobin, glucose and diphtheria toxin.

Therapeutic failure of penicillin when applied to nasal mucous membranes is sometimes attributed to the inability of the antibiotic to penetrate mucous surfaces and thus reach deep-seated foci of infection. Som[3] and his associates of New York's Mount Sinai Hospital therefore tested the possibility of enhancing the penetration of penicillin through mucous membranes by the use of hyaluronidase.

Two groups of patients selected for these tests included 12 with chronic suppurative disease of the maxillary sinus and 3 clinically free from sinus disease. After preliminary cocainization and routine cleansing, a cannula was inserted into the maxillary sinus. The sinus was irrigated with isotonic sodium chloride solution and thoroughly drained. Two hundred thousand units of crystalline penicillin G, dissolved in 2 to 3 cc. of saline solution, was then instilled into the sinus. An absorbable gelatin sponge pack was inserted into the middle meatus as a safeguard against leakage. Blood samples were titrated for penicillin, 30, 60 and 120 minutes later. In 3 of the 12 with infection penicillin was not demonstrable in the circulatory blood. In most of the other cases from 0.1 to 0.5 unit of penicillin per cubic centimeter was detected, the average being about 0.3 unit per cubic centimeter.

A few days later the same persons were retested with a similar dose of penicillin plus 20 to 42 turbidity-reducing units of hyaluronidase. In 2 of the patients in whom circulating penicillin could not be demonstrated in the first test, the addition of hyaluronidase resulted in a significant concentration of penicillin in the blood stream. In other cases the average penicillin titer was two to three times higher than in the first test.

---

[1] Duran-Reynals, F.: Compt. rend. Soc. de biol. **99:** 6 (June) 1928; J. Exper. Med. **50:** *327* (Sept.) 1929.

[2] Chain, E., and Duthie, E. S.: Nature **144:** *977* (Dec. 9) 1939; Brit. J. Exper. Path. **21:** *324* (Dec.) 1940.

[3] Som, M. L.; Schneierson, S. S., and Sussman, M. L.: Proc. Soc. Exper. *Biol. & Med.* **70:** *96 (Jan.) 1949.*

Som concludes from these data that hyaluronidase increases significantly the penetration and diffusion of penicillin through nasal mucous membranes. Whether or not it also causes a more effective outward drainage from the deeper layers of the nasal tissues was not determined. The investigators noted definite clinical improvement in some of the patients treated with the penicillin-hyaluronidase mixture.

---

### CAN THE RED CROSS SURVIVE?

In his keynote address to the 24th Annual Convention of the American National Red Cross last month President Basil O'Connor spoke boldly on present trends in charity and welfare. Tracing the trends of development and action of voluntary association for the alleviation of human suffering, he inquired as to whether or not this is an outmoded and inefficient method. "Must we consider the possibility," he asked, "that a compulsory system of humanitarian activity under state control is the best solution?" Mr. O'Connor considered that the expansion of governmental authority has taken place in the main because of the failure of private individuals or private groups to do certain jobs which society feels must be done. Modern fascist and communist dictators, said Mr. O'Connor, have risen to power on the ruins of the political and religious groups, the trade unions and the fraternal orders. They had to destroy these in order to clinch their power over the masses. Totalitarian systems of government dare not risk the existence of free and spontaneous action such as that resulting from voluntary associations.

In a democracy voluntary associations must play an essential role, warned President O'Connor, in preserving freedom in a society which our industrial technology is driving into an ever greater centralization. A part of the mission of the Red Cross is to protect free association because it is vital to free society.

Pursuing the theme, the President of the American Red Cross sounded a warning against the tendency to remove from voluntary associations the spirit of individualism that animates them in their work:

> Some high-minded citizens today are taking another view. They believe that the collection of funds for health and welfare purposes should be centralized; that individual organizations should lose identity; and that private humanitarian activity should thereby be put on a consolidated and allegedly more efficient basis. The motives behind this proposal may be good, but its proponents overlook the dangers inherent in its denial of the fundamental philosophy. In our opinion, these dangers might come to threaten in our land the entire tradition of voluntary health and welfare work.

If this nation were to remove from the sphere of voluntary action the whole experience of relief and assistance and transform it into "a massive, mechanical system of invisible deductions and automatic contributions," people would be deprived of the individual exercise of the impulse of generosity. Mr. O'Connor states emphatically his personal belief in the desirability of voluntary versus collective compulsory interest in the care of the sick and the unfortunate.

The voluntary associations which support many aspects of medical service in the United States are a fundamental, vital and in some ways unique feature of the American medical scene. While such organizations exist in other countries, they have not in any other nation achieved the power, the funds, the importance or the ability to do good that they have attained in the United States. These attributes are a reflection of their dynamic leadership. They are the result of the self-sacrificing, exhausting and highly intelligent benefaction of time, effort and ability given by men who could have achieved perhaps far more for themselves by selfish devotion to their own interests.

### TELEVISION AT THE ATLANTIC CITY SESSION

The color television demonstration presented by the faculty of the University of Pennsylvania Medical School and the staff at the Atlantic City Hospital, with the cooperation of Smith, Kline and French, Laboratories, attracted a host of viewers. The program was beamed on a closed circuit from the local hospital to the convention hall. Ten receivers with 12 inch screens projected a color image. Occasionally the color image was changed to black and white, and the contrast was striking. Surgical procedures reproduced satisfactorily; however, there is room for improvement as far as delicate skin lesions are concerned. As a teaching medium color television has great potentialities. Television will not replace motion pictures. Television is a form of visual education which could be coordinated and integrated with other technics of teaching. This new teaching device comes at a time when medical educators are beginning to appreciate and understand the intelligent use of motion pictures. The sponsors of the color television program are to be complimented for their contribution to the advancement of medical teaching. Physicians attending this session have witnessed another milestone in the evolution of visual education. The use of television in making roentgenograms clearer and sharper and its value in making a diagnosis was presented at the Annual Meeting by the University of Illinois College of Medicine in cooperation with E. R. Squibb & Sons and RCA Victor Division, Radio Corporation of America. An extremely high degree of accuracy can be obtained in reproducing roentgenograms on television by varying the density and contrast controls on the receiver. Details of the original film can be brought out much more clearly. The films were transmitted over a closed circuit from a room adjacent to the receiving sets.

## CHOLINE AND THE PREVENTION OF EXPERIMENTAL AORTIC ATHEROSCLEROSIS

The effectiveness of choline in preventing the deposition of fat in the livers of depancreatized dogs and of rats fed diets high in fat or in cholesterol is now well established. Choline is also effective in the removal of such fat deposits after they have been formed. The question is thus raised as to whether choline might also prevent or remove other types of lipid deposits, such as aortic atherosclerosis produced experimentally by feeding of cholesterol. Several earlier investigations of this problem have resulted in contradictory results, perhaps due to the rise of varying proportions of choline to cholesterol or to varying lengths of periods of feeding and observation. The problem has recently been subjected to a careful reinvestigation.[1] Rabbits were fed a regular diet into which was incorporated cholesterol (25 animals) or cholesterol plus choline (29 animals) given at two levels, 0.5 or 1.0 Gm. daily. The blood cholesterol levels were determined biweekly in the animals of each group, and at intervals varying from forty-five to one hundred days necropsies were done on the animals and a macroscopic examination was made for atherosclerosis in the aorta and for fatty changes in the liver. Hypercholesterolemia was observed to the same degree in the rabbits of both groups. However, at necropsy between the fortieth and the eightieth day of the experiment none of the choline-treated animals showed macroscopic atheroma in the aorta, whereas 10 of 11 control rabbits examined at the same time did so. Some degree of atherosclerosis did develop in 12 of 16 rabbits fed cholesterol plus choline for periods exceeding eighty days, but the extent of the lesion was less than that found in the group not treated with choline. The author's conclusion that choline exhibits a protective action against the development of experimental atherosclerosis in rabbits fed cholesterol thus appears warranted.

## SYNTHESIS OF NICOTINIC ACID

New experimental and clinical evidence has been presented[1] for the current view of the transformation of tryptophane to nicotinic acid; the type of carbohydrate in the diet and the nature of the amino acid mixture being consumed seem to be factors in the extent of this transformation. The mechanism of the change has also received attention; although vitamin $B_6$ is required to promote the change of tryptophane to kynurenine and then to kynurenic acid in the rat,[2] it has no apparent influence on the tryptophane–nicotinic acid metabolism. Again, on the basis of differential time studies, the Duke investigators[3] conclude that, after growth has been depressed by adding gelatin to a low protein, nicotinic acid–poor ration, the favorable effect of added tryptophane is through its formation of nicotinic acid and not through its action as an essential, protein-building amino acid. As tryptophane, kynurenine and 3-hydroxyanthranilic acid support growth in mutant strains of Neurospora[4] and tryptophane and 3-hydroxyanthranilic acid replace nicotinic acid for the growth of rats,[5] tryptophane is apparently transformed to nicotinic acid through 3-hydroxyanthranilic acid as an intermediate step. The change from the amino acid to the vitamin can occur without the mediation of the intestinal flora, as indicated by the failure of enterectomy to prevent it.[6] Some support to the universality of the relationship is given by the observation of Nason[7] that the addition of tryptophane to the nutrient medium in which corn embryos were grown resulted in a 60 per cent increase in the content of nicotinic acid in the embryos. The demonstration of the details of the mechanism of the transformation of tryptophane to nicotinic acid has been made largely on a species which apparently can ordinarily synthesize its own nicotinic acid; further investigation will show whether or not in man this change is brought about by the same mechanism.

## THE HEALTHIEST ARMY IN THE WORLD

The July issue of *Life of the Soldier and the Airman*, a periodical published by the Adjutant General, is a well illustrated edition devoted to the Medical Department of the Army and comprising pictures of Army hospitals, leaders of the various corps of the Medical Department and activities carried on by the Medical Department in the hospitals and in the field. The United States Army was during World War II, and is at present, the healthiest army in the world. This exceptional health record is attributed to: (1) effective measures of preventive medicine; (2) strict sanitation in matters of food, housing and personal hygiene of the soldier, purification of water and insect and rodent control; (3) the development and application of new drugs, and (4) medical personnel expertly trained and imbued with only one aim—to save lives. In World War I, the incidence rate of tetanus is said to have been 13.4 per cent per 100,000 men; in World War II, the soldier was immunized against tetanus and the rate was 0.44 per cent per 100,000 men. In the 12 cases which occurred in World War II, 8 of the patients had either not been immunized or had not completed their immunization. During the Civil War the Union Army, with less than a million men, had 75,368 cases of typhoid compared with only 42 cases in World War II, when more than ten million American men and women were enrolled. An Army medical officer, Major Carl Darnall, in 1910, built the first apparatus for forcing chlorine gas through water, a practice which is now "worldwide and which has prevented untold millions of cases of typhoid, cholera, and the dysenteries." This issue also contains tributes to the Medical Department by the Honorable Louis Johnson, Secretary of Defense; Major General Raymond W. Bliss, Surgeon General of the Army; Rear Admiral C. A. Swanson, Surgeon General of the Navy, and Major General Malcolm C. Grow, the Air Surgeon.

*(From a Special Correspondent)*

July 18, 1949.

### Ewing Denies Welfare Department Would Propagandize for Socialized Medicine

Testifying on July 21 before the Senate Committee on Expenditures in support of establishment of a Department of Welfare in the President's Cabinet, Federal Security Administrator Oscar Ewing denied that facilities of the Department would be "used" to promote sentiment for socialized medicine. His statement to that effect came in the course of questioning of the witness by Senator John L. McClellan (Democrat, Arkansas), chairman, and Senators Irving M. Ives (Republican, New York), Russell B. Long (Democrat, Louisiana), Margaret Chase Smith (Republican, Maine) and James O. Eastland (Democrat, Mississippi).

Senator McClellan, who served as a member of the Hoover Commission, is committed in favor of a Department of Welfare which would take over functions now handled by the Federal Security Agency. He is, moreover, one of the Senate's most articulate opponents of compulsory health insurance. As soon as Mr. Ewing had completed the reading of his prepared statement, the committee chairman expressed his anxiety over charges that conversion of FSA into an executive department would hasten the advent of health insurance. He asked Mr. Ewing whether it was his plan to take advantage of the wider authority conferred by Cabinet status to promote such a program.

"There is nothing in this plan that would add to what I might or might not do," replied Mr. Ewing. "It is up to Congress to decide on national health insurance."

Emphasizing that the President has never told him that he will be the first Secretary of Welfare provided that Congress does not veto the White House recommendation that a new department be created, the Federal Security Administrator told the committee that he could foresee no particular advantage —as far as pressing the fight for health insurance is concerned —that would accrue from setting up a Department of Welfare.

When Senator Ives asked Mr. Ewing whether his elevation to a secretaryship would bring about a change in his attitude toward national health insurance, the FSA chief replied promptly, "No, I believe in it."

The New York Senator asked the witness whether, with the Office of Education under his control, the opportunity to propagandize for socialized medicine through "informal education" mediums might not be seized on.

"I don't see how the Secretary would have any more control over this than the Federal Security Administrator," Mr. Ewing responded.

Senator Andrew F. Schoeppel (Republican, Kansas), stating that he had received hundreds of telegrams expressing fear of a step-up in propaganda operations if the department is established, demanded to know whether counsel of the various states would be taken and cooperative relations cultivated by the Department of Welfare. Mr. Ewing answered emphatically in the affirmative.

Scheduled to testify July 22 on the reorganization plan were Dr. James R. Miller, for the American Medical Association; Dr. E. Harold Gale and Francis J. Garvey, for the American Dental Association; Dr. Charles R. Henry, for the Arkansas Medical Society, and Dr. Robert E. S. Young, for the Association of American Physicians and Surgeons.

### Proponents of D. C. Animal Experimentation Bill Disheartened

Washington branch of National Society for Medical Research this week issued a statement expressing the belief that its efforts to obtain Congressional passage of an animal experimentation bill are doomed to failure. The bill in question is S. 1703, legalizing the transfer to local hospitals and medical schools of unclaimed animals held beyond a certain period at the District of Columbia dog pound. Public hearings on the measure were held last spring by a Senate subcommittee whose chairman is Senator Margaret Chase Smith (Republican, Maine).

Issuance of the pessimistic announcement came in the wake of a meeting held by supporters of the bill on July 11 in the auditorium of the Medical Society of the District of Columbia. Principal speaker at the meeting was Dr. Andrew C. Ivy, who is secretary-treasurer of the National Society for Medical Research. Dr. Ivy reported that doctors and scientists have failed to express themselves affirmatively on the bill in sufficient numbers; therefore S. 1703 probably will languish in committee.

"The preposterous and dangerous situations which the antivivisection movement has produced is really the scientists' fault," he stated. "Our lack of effort in the past has enabled the antivivisectionists to achieve their present restrictions on research and teaching. It would be more than a tragedy if further inertia were to continue and this important legislation to suffer a defeat."

### Drs. Warren and Gregg Interrogated on Capitol Hill

Medical effects of atomic bomb explosions were described to the Joint Committee on Atomic Energy on July 11 by Dr. Shields Warren, Boston pathologist and director of the Division of Biology and Medicine, Atomic Energy Commission. Accompanying him to the Congressional hearing was Dr. Alan Gregg, in his capacity as chairman of the division's advisory committee. Members in attendance at the session, and who questioned the two physicians on various aspects of radiation injury, were Senators McMahon (chairman), Hickenlooper, Vandenberg and Knowland, and Representatives Durham (vice chairman), Van Zandt, Price and Elston.

In the course of questioning, Dr. Warren disclosed that the Atomic Energy Commission medical research program stands in danger of curtailment as a result of reduction in the budget for 1950. In this connection, Senator McMahon described as "silly" the following passage in the Senate Appropriations Committee's report on the Atomic Energy Commission's proposed budget for the fiscal year ending June 30, 1950:

"Curtailment of activity is thus recommended to be made in other fields of Commission operations, such as administration, community programs, biology and medicine, physical research, and to such aspects of reactor development as are not immediately necessary for national security."

### Dispute Over Hospital Control Settled

Late in July the Veterans Administration disclosed that differences between Administrator Carl R. Gray Jr. and Dr. Paul B. Magnuson, chief medical director, over administration of veterans hospitals had been settled amicably. Administrator Gray has conceded that responsibility for over-all operation of the institutions should be vested in the chief medical director. Henceforward the managers of hospitals will be responsible directly to Dr. Magnuson, instead of to Administrator Gray as was the previous policy.

### Hearings Conducted on Federal Rehabilitation Commission

A four day series of public hearings on proposed legislation to establish a new Federal Commission on Services for the Physically Handicapped was opened by a subcommittee of the House Committee on Education and Labor on July 12. The bill at issue (H.R. 3095) would take the government's activities in medical and vocational rehabilitation of the physically handicapped out of Federal Security Agency and give control to the new commission. FSA opposes the plan and offers instead a bill (H.R. 5577), introduced on July 11 by Chairman John Lesinski (Democrat, Michigan) of the House Committee on Education and Labor, designed to broaden the scope of federal services to the disabled under present policies of administration.

# Medical Legislation

## STATE LEGISLATION

### Alabama

**Bills Introduced.**—H. 4 proposes to authorize the state board of health *to construct, equip, maintain and regulate the operation of* **four tuberculosis hospitals** and to make rules and regulations governing the efficient and uniform operation of these hospitals. H. 7 proposes to authorize and require the state board of health to make **free cancer examination** facilities available to the residents of Alabama. H. 498 proposes to require attending physicians and hospitals or other institutions **to report deaths** resulting from or which might have resulted from violent or unlawful causes or from poisoning to the coroner of the county in which the death occurs. H. 635 proposes the enactment of a **licensing law for hospitals**, sanatoriums, rest homes, nursing homes and related institutions. H. 641 proposes to make it unlawful for any employer to require an employee or an applicant for employment to pay the **cost of a medical examination** or any cost for furnishing records required as a condition of employment by the employer. S. 86 proposes the establishment of an institution for the treatment and **rehabilitation of alcoholics.** S. 160, relating to the state program of cancer diagnosis, proposes that all females within the age limit prescribed by the state board of health shall be urged *to report voluntarily during* **Cancer Detection Month** *to a duly licensed* physician of their choice for an official examination. S. 316 proposes to authorize the state board of medical examiners to provide for the **licensing of clinical laboratories**, clinical laboratory directors and medical technologists. A medical technologist is defined as a person other than a physician and surgeon who under the direction of a physician and surgeon or under the direction of a clinical laboratory director performs the technical procedure called for in a clinical laboratory. A clinical laboratory is defined as a place organized and operated for the practical application of one or more of the fundamental sciences by the use of specialized apparatus, equipment and methods for the purpose of obtaining scientific data which may be used as an aid to ascertain the presence, progress and source of disease. S. 375 proposes the enactment of a **hospital licensing law** under the direction of the state board of health, and exempts from such law hospitals operated by the federal government and state mental hospitals. S. 408, to amend the law requiring **tuberculosis examinations** of certain persons in Alabama, proposes that all persons *within the age limits specified by the state board of health shall* have physical and roentgenologic examinations or otherwise be tested for tuberculosis during such periods or at such times as shall be designated by the state board of health.

**Bills Enacted.**—H. J. Res. 16 has become Act No. 111 of the Acts of 1949. It memorializes the Congress of the United States to use whatever means may be at their disposal to defeat all attempts, either direct or indirect, to **socialize medical care** in the United States. H. J. Res. 21 has become Act. No. 9 of the Acts of 1949. It requests the senators and representatives in Congress from the state of Alabama to actively support *the purposes of the Toby bill providing for the setting up of a National* Foundation for the study of **multiple sclerosis.** S. 125 has become Gov. No. 7 of the Laws of 1949. It makes it a felony for any person to introduce **benzedrine** or any habit forming drug or narcotic into a penal institution unless it was purchased and distributed by the prison physician and possessed in accordance with the orders of such physician.

### Connecticut

**Bill Enacted.**—H. 762 has become Public Act No. 77 of the Acts of 1949. Relating to the circumstances under which a person **licensed to practice chiropractic** in some other state may obtain a certificate of approval in Connecticut without examination, the law provides that the examining board shall not grant a certificate of approval without examination to any person who shall have been refused a certificate by the state board of healing arts because of failure to pass the examination or because of failure to satisfy the board of any other requirement, until such person shall have satisfied the state board of healing arts that he has met the conditions required of him and until he shall have received a certificate from such board. H. 1625 has become Public Act No. 150 of the Acts of 1949. It permits the practical training of **medical and dental students** prior to their receiving licenses to practice their respective professions. The training may be given under the supervision of a licensed dentist or physician in a dental or medical school or in a hospital, infirmary, clinic or dispensary affiliated with such school. S. 546 has become Public Act No. 104 *of the Acts of 1949. It grants* to **medical examiners** the same authority as is already had by coroners so far as determining when an autopsy shall be ordered is concerned. S. 1046 has become Public Act No. 171 of the Acts of 1949. It amends the exemption section of the medical practice act by eliminating therefrom persons **practicing massage or Swedish movement.**

### Florida

**Bills Enacted.**—H. 24 became law without approval June 13, 1949. It requires **chiropractors** to renew their licenses annually. H. 26 became law without approval June 13, 1949. It amends the **chiropractic act** relating to the qualifications of applicants and the procedure for the suspension or revocation of chiropractic certificates. H. 187 was approved June 13, 1949. It authorizes the board of commissioners of state institutions to select and acquire a site for a hospital for the treatment of **chronic alcoholics.** H. 423 became law without approval June 13, 1949. It authorizes the board of commissioners of state institutions to employ a chief psychiatrist and additional psychiatrists who shall have fully *recognized and* accredited training and experience in the practice of medicine and psychiatry, and who shall be attached to the medical staff of the Florida State Hospital. The **chief psychiatrist** shall be a reputable well educated physician, a graduate of a recognized class A medical school (as classified by the American Medical Association and the Association of American Medical Colleges) and a certified psychiatrist, and shall have had at least 5 years' experience in the actual practice of psychiatry, at least 2 years of which must have been in an institution for the care and treatment of the mentally ill. H. 828 became law without approval June 13, 1949. It amends the law relating to **hospital service plans** by providing that the term "medical and/or surgical service plan" shall *include the contracting for the payment of fees toward, or furnishing of*, professional services authorized or permitted to be furnished by a duly licensed doctor of medicine. H. 1331 became law without approval June 13, 1949. It provides for the licensing and regulating of **private nursing homes.** S. 550 was approved June 7, 1949. It provides that the tuberculosis board shall provide adequate facilities for the compulsory isolation and treatment of persons found to be suffering from ***tuberculosis.***

### Massachusetts

**Bills Introduced.**—H. 2540 proposes regulations for the organization of nonprofit ***hospital service corporations.*** H. 2580 proposes the creation of a special commission to make a further study relative to **regulating advertising** in connection with the sale of eyeglasses, lenses or eyeglass frames.

**Bill Enacted.**—H. 913 has become chapter 442 of the Laws of 1949. It amends the **workmen's compensation act** by providing that any physician who has testified either for an insurer or a claimant at least three times in the preceding twelve months shall not be eligible to be appointed by *the compensation commissioner as an impartial physician.*

### New Hampshire

**Bill Enacted.**—S. J. Res. 7 was approved June 21, 1949. It provides for the creation of a committee to study and analyze **hospital care and rates** *to be paid by the state to hospitals for services to recipients of* public assistance.

### Pennsylvania

***Bills Enacted.***—*H. Res. 74 was adopted April 27, 1949. It provides* for the creation of a commission to study and revise, among other things, **laws relating to mental health.** H. 144 has become Act No. 106 of the Acts of 1949. It authorizes the Department of Public Instruction or any of its departmental administrative boards, commissions or offices, on the advice of the attorney general, to maintain an action for an injunction against any person to restrain or prevent his practicing any *profession in the state* **without a license** whenever a license to engage in such activity is required by law. S. Res., Serial No. 35 was adopted April 11, 1949. It provides for the creation of a **commission to investigate the problem of medical care**, including the number of medical students available, the number of medical students able to attend graduate medical school, the number of medical doctors required for a minimum of services to the people and the part the commonwealth should play in making medical education available if needed. This commission should make a report to the next general assembly. S. 330 has become Act No. 87-A of the Laws of 1949. It provides an appropriation to the Department of Health of $150,000 for the purpose of **advancing research and demonstrations** on improvement in nutritional status and consequent improvement in physical well-being of civilians based on research work now in progress. S. 508 has become Act No. 79-A of the Acts of 1949. It provides an appropriation of $200,000 to the Department of Health for the maintenance and purchase of operating equipment of the **Institute for Cancer Research**, Incorporated.

# Coming Medical Meetings

Aero Medical Association, New York, Aug. 29-Sept. 2. Dr. Thomas H. Sutherland, 214 S. State St., Marion, Ohio, Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va., The Homestead, Sept. 8-10. Dr. Leroy A. Calkins, University of Kansas Medical Center, Kansas City 3, Kan., Secretary.

American Congress of Physical Medicine, Cincinnati, Netherlands Plaza Hotel, Sept. 6-10. Dr. Richard Kovács, 2 E. 88th St., New York 28, Secretary.

American Roentgen Ray Society, Cincinnati, Sept. 4-7. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Iowa, Secretary.

Colorado State Medical Society, Denver, Shirley-Savoy Hotel, Sept. 20-23. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver, Executive Secretary.

International Congress of Biochemistry, Cambridge, England, Aug. 19-25. Lt. Col. Francis J. Griffin, 56 Victoria St., London, W.C.1, Organizer.

International Neurological Congress, Paris, France, Sept. 5-10. Dr. Raymond Garcin, 19 rue de Borgogne, Paris, General Secretary.

Michigan State Medical Society, Grand Rapids, Pantlind Hotel and Civic Auditorium, Sept. 21-23. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

Montana State Medical Association, Butte, Aug. 1-4. Dr. Herbert T. Caraway, 115 N. 28th St., Billings, Secretary.

National Medical Association, Detroit, August 8-12. Dr. John T. Givens, 1108 Church St., Norfolk, Va., Secretary.

Utah State Medical Association, Salt Lake City, Sept. 1-3. Dr. Ray T. Woolsey, 42 S. Fifth East St., Salt Lake City 2, Secretary.

Vermont State Medical Socie [illegible] Dr. James P. Hammond, 542 Main St., [illegible]

Washington State Medical A[illegible] Hotel, Sept. 11-14. Dr. James W. Havil[illegible] Bldg., Seattle, Secretary.

West Virginia State Medical Association, White Sulphur Springs, The Greenbrier, Aug. 4-6. Mr. Charles Lively, 1031 Quarrier St., Charleston, Executive Secretary.

Wyoming State Medical Society, Casper, Sept. 12-14. Dr. George H. Phelps, 1606 Capitol Avenue, Cheyenne, Secretary.

# GOVERNMENT SERVICES

## SECRETARY OF DEFENSE

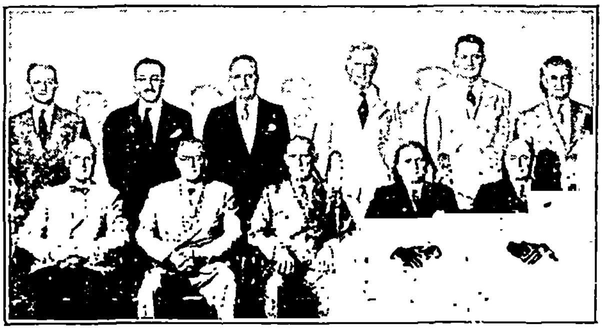
### HAWLEY BOARD SUBMITS FINAL REPORT

Concluding eighteen months of study of problems involved in coordinating medical activities of the National Military Establishment, the Committee on Medical and Hospital Services of the Armed Forces (Hawley Board) submitted its final report to Secretary of Defense and was dissolved July 6. Dissolution of the committee had been ordered when Dr. Raymond B. Allen assumed office July 6 as director of the newly established NME Medical Services Division. Its twenty-two subcommittees were transferred to the Medical Services Division. These subcommittees are composed of more than 100 officers and civilian personnel of the three military medical departments with long experience in problems involved in coordination of the Medical Services. The Hawley Board, in addition to Dr. Paul R. Hawley, its chairman, included the surgeons general of the Army, Navy and Air Force. Rear Admiral Joel T. Boone, U. S. Navy, was Executive Secretary.

During its tenure, the committee submitted twenty-two reports, containing more than 200 recommendations, many of which have been put into effect; others are in process of implementation. Some of the areas in which the committee conducted studies included hospitalization, standardization of preventive medicine practices and procedures, medical research, professional services, medical supply, standards of medical nomenclature and aviation medicine. Included in the committee recommendations also was one for a coordinating agency to function, as does the newly established Medical Services Division, at the level of the Office of the Secretary of Defense. In its studies, the committee visited about 150 medical installations of the three armed forces within the Continental United States, in the Panama and Caribbean Area, in Hawaii, Guam, Japan, the Aleutian Islands and Alaska.

### MEDICAL ADVISORY COMMITTEE

The appointment of the Armed Forces Medical Advisory Committee to act in an advisory capacity to the Secretary of Defense in the fields of medicine and the allied professions was recently announced. The Secretary has asked the committee to submit recommendations on general policies and programs for the National Military Establishment as a whole; on the development of medical services capable of supporting the needs of the armed services efficiently; the elimination of unnecessary duplications in the medical departments of the armed forces, and the development of the maximum continuing cooperation between the members of the civilian and allied professions in the armed services. In addition to advising the Secretary of Defense, the Committee was directed to give advice on medical problems, on request, to the Secretaries of the Army, Navy and Air Force, the Chairmen of the Munitions Board and the Research and Development Board or the head of any other board or agency in the National Military Establishment.



Armed Forces Medical Advisory Committee.—(L to R, seated) Dr. Paul Titus, Pittsburgh; Dr. Raymond B. Allen, Seattle; Mr. Charles P. Cooper, New York; Dr. Richard L. Meiling, Columbus, Ohio; Dr. Edward D. Churchill, Boston. (L to R, standing) Mr. J. Joseph Whelan, Executive Secretary of the Committee; Dr. Michael DeBakey, Houston, Texas; Daniel F. Lynch, D.D.S., Washington, D. C.; Dr. Maurice C. Pincoffs, Baltimore; Dr. Howard A. Rusk, New York; Dr. Francis J. Braceland, Rochester, Minn. Members of the Committee not shown above are: Walter H. Scherer, D.D.S., Houston, Texas, and Dr. Paul R. Hawley, Chicago.

The new committee is expected to examine questions of basic policy affecting the Medical Departments of the armed forces and thus succeed, rather than supersede, the existing Ad Hoc Committee on Medical and Hospital Services (Hawley Board) and to study and make recommendations for improving the services provided by existing medical organizations in the National Military Establishment. In addition to the civilian members of the Board, the Committee members are also: Major Gen. Raymond W. Bliss, Surgeon General of the Army; Rear Admiral Clifford A. Swanson, Surgeon General of the Navy, and Major Gen. Malcolm C. Grow, the Air Surgeon.

## NAVY

### EXAMINATION FOR THE REGULAR CORPS

The Navy Department announces that examinations for the selection of candidates for appointment as lieutenant (jg) in the Medical Corps will be conducted at Naval hospitals, September 12-16. Graduates of approved medical schools in this country and Canada who have completed an internship or who will have done so in four months of the examination date and who are less than 32 years of age may be examined for appointment. The total pay of this grade for officers with dependents is $5,011 a year and for those without dependents, $4,575.50. Details may be obtained from the Bureau of Medicine and Surgery, Navy Department, Washington 25, D. C.

### NEW REGULAR OFFICERS

The following lieutenants (jg) of the Medical Reserve Corps have accepted appointments in the regular Navy Medical Corps: Harry C. Alfred, Kansas City, Mo.; Jules H. Bogaev, Philadelphia; Paul D. Doolan, Hamden, Conn.; Frederick W. George III, Burgettstown, Pa.; Jerome Imberg, Richmond, Va., and Charles W. Lewis, Greensboro, N. C.

### DUTY UNDER INSTRUCTION

Nominations for duty under instruction in the Navy's Graduate Medical Training Program have been made for the following regular Navy medical officers:

Lieut. Comdr. William W. Manson to a Residency in Obstetrics and Gynecology at the Naval Hospital, NNMC, Bethesda, Md.

Lieut. (jg) Charles H. Beach to a Residency in Urology at the Naval Hospital, NNMC, Bethesda, Md.

Lieut. (jg) Benjamin L. Crue to a Residency in General Surgery at the Naval Hospital, Oakland, Calif.

Lieut. (jg) Henry L. Hook to a Residency in Internal Medicine at the Naval Hospital, Philadelphia.

Lieut. (jg) Joseph L. Maioriello to a Residency in Pediatrics at the Naval Hospital, NNMC, Bethesda, Md.

Lt. (jg) William R. Rundles to a Residency in General Surgery at the Naval Hospital, Chelsea, Mass.

Lieut. (jg) William L. Thomas to a Residency in Obstetrics and Gynecology at the Naval Hospital, Oakland, Calif.

# PUBLIC HEALTH SERVICE

## $1,200,000 FOR HEART DISEASE RESEARCH

Grants of more than $1,200,000 by the National Heart Institute to support research on heart disease in medical schools and hospitals were announced July 15 by the Federal Security Administration. The grants were approved by Surgeon General Scheele of the Public Health Service following recommendation by the National Advisory Heart Council. According to Dr. C. J. Van Slyke, director of the National Heart Institute, the grants comprise only a portion of the federal funds to be awarded for such research during the current fiscal year. Additional grants for new research and for construction of facilities and laboratories for research are expected to be announced shortly. Awarded to finance 85 research projects now being carried on in 45 institutions, the present grants will be used to continue investigations into the causes, treatment and prevention of heart disease.

Presently under study and supported by the grants announced *are projects investigating the role of heredity in coronary* heart disease, the effect of diet on high blood pressure and arteriosclerosis and the usefulness of new drugs in helping to relieve heart disease symptoms. Evaluations and studies are also being made of instruments, such as the ballistocardiograph and the electrokymograph, to improve their usefulness as diagnostic tools in heart disease.

## HOSPITAL PROJECTS COMPLETED

The Public Health Service reports that as of May 1, 1949, 768 projects have received initial approval under the National Hospital Construction Program. Final approval had been given 336 applications out of this total, and these are out on bid or under contract. The total cost of the 336 applications was estimated at $185,256,278, of which the federal share was estimated at $56,974, 839. The following fourteen of the projects have been completed and are in operation:

| Location | Facility | Total Cost | Federal Share |
|---|---|---|---|
| Birmingham, Ala. | Jefferson County Health Center | $996,470 | $332,156 |
| Live Oak, Fla. | Suwanee County Hospital | 308,242 | 93,685 |
| Franklin, Ga. | Heard County Memorial Hospital | 15,525 | 5,175<br>(equipment only) |
| Baltimore | State Bacteriology Laboratory | 100,440 | 33,480 |
| West Point, Miss. | Clay County Health Center | 70,249 | 23,083 |
| Cut Bank, Mont. | Glacier County Memorial Hospital | 297,692 | 98,244 |
| Hebron, Neb. | Thayer County Memorial Hospital | 86,817 | 12,939<br>(equipment only) |
| *Ahoskie, N. C.* | *Roanoke-Chowan Hospital* | *139,652* | *46,550* |
| Oklahoma City | State Health Department Laboratory | 65,847 | 21,449 |
| Nowata, Okla. | Nowata Hospital | 149,418 | 48,139 |
| Oklahoma City | Edwards Memorial Hospital (Negro) | 125,550 | 41,850<br>(equipment only) |
| State Park, S. C. | South Carolina State Hospital (Mental) | 17,785 | 5,928<br>(steam plant) |
| Anderson, S. C. | Anderson County Health Center | 164,002 | 54,667 |
| Marshall, Texas | Kahn Memorial Hospital | 94,451 | 31,483 |

# VETERANS ADMINISTRATION

## 23,260 VETERANS STUDY MEDICINE

A Veterans Administration study of the principal courses and employment objectives of 2,535,385 veterans enrolled in schools and job training establishments under the G.I. Bill and Public Law 16 on Dec. 1, 1948 shows that veteran-students in the medical sciences represented 3 per cent of the total number of all trainees. Of the 78,143 veterans enrolled under the G.I. Bill, more than one third, or 23,260, were taking courses in medicine and surgery. The rest were studying in the following fields:

| | |
|---|---|
| Dentistry | 7,603 |
| Nursing | 3,955 |
| Osteopathy | 918 |
| Pharmacy | 11,668 |
| Veterinary medicine | 2,036 |
| Chiropractic | 3,287 |
| Optometry | 3,374 |
| Chiropody | 1,107 |
| Physical therapy | 325 |
| Occupational therapy | 156 |
| Laboratory technic | 1,240 |
| Dental hygiene | 103 |
| Dental mechanics | 2,738 |
| Medical service | 250 |
| Public health | 399 |
| Bacteriology | 600 |

Premedical, predental and preveterinary students numbered 14,784. Seventy per cent of these, or 10,487, were in premedical courses.

Under Public Law 16—an act providing training for those with service-connected disabilities—veterans training in the medical professions numbered 5,168.

Of these, 1,540 were enrolled in medical courses; 1,207, pharmacy; 904, dentistry; 505, chiropracty; 469, veterinary; 194, nursing, and 349, medical services.

Eligibility for G.I. Bill training consists of (1) active military service some time between Sept. 16, 1940, and July 25, 1947; (2) service of at least 90 days, or a discharge for a service-connected disability if released before 90 days' service, and (3) a discharge under conditions other than dishonorable. For Public Law 16, requirements are (1) military service between the 1940 and 1947 dates; (2) a discharge other than dishonorable; (3) a compensable service-connected disability, and (4) VA's determination that training is necessary to overcome a handicap. While in training, veterans may receive a subsistence allowance from VA.

## NEW HOSPITAL ON CHICAGO'S WEST SIDE

The Veterans Administration is accepting bids for the construction of a 500 bed Veterans Administration general hospital in the medical center district on Chicago's west side. After July 20, drawings and specifications may be obtained by writing to the Technical Service, Veterans Administration, Washington, D. C. There will be a main hospital building, 4,274,000 cubic feet in size, recreation hall and chapel, nurses' quarters, apartment, boiler house, electrical substation, attendants' quarters and connecting corridor. The buildings will have brick-faced exterior walls with stone trim backed with hollow tile, and reinforced concrete floors.

## PERSONALS

Dr. George T. McMahan has been appointed manager of the Veterans Administration Center in Waco, Texas, and Dr. William K. Freeman as manager of the Hospital in Gulfport, Miss. Dr. McMahan served four years in the Army during World War II and Dr. Freeman has been with the Veterans Administration for the last thirteen years.

Miss Dorothy Rouse has been appointed chief of occupational therapy for the Veterans Administration Physical Medicine Rehabilitation Service. Miss Rouse has been with the Veteran's Administration and its predecessor organizations since 1919.

Elon Henry Clark, former assistant professor of medical art and photography at Duke University, has joined the Veterans Administration's Department of Medicine and Surgery as Chief, medical art photography section, research and education service.

The following physicians have been added to the staff of the regional office of the Veterans Administration at Boise, Idaho: Raymond P. Westover, Basil Duke Buford and Hans J. Feitis.

Dr. Leslie H. Wright has been appointed manager of the McGuire Veterans Hospital at Richmond, Va., succeeding Dr. Edmund M. Ellerson, who becomes chief of professional services at the Veterans Hospital, Alexandria, La.

Dr. Peter A. Volpe became manager of the Veterans Hospital at Dwight, Ill., on July 1, succeeding Dr. Septimus T. Taylor, who retired. Dr. Volpe is a grdauate of Ohio State University College of Medicine and is certified by the American Specialty Board in Physical Medicine.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## CALIFORNIA

**Dr. Northrop Appointed Visiting Professor.**—John Howard Northrop, Ph.D., Nobel Laureate, has been appointed visiting research professor of bacteriology on the Berkeley campus of the University of California. Dr. Northrop comes to Berkeley under a special arrangement between the university and the Rockefeller Institute for Medical Research. Dr. Northrop is one of the world's pioneers in the chemistry of the proteins. He achieved the first crystallization of the proteolytic enzymes.

**Diphtheria in San Francisco.**—A total of 93 local and 3 nonlocal cases of diphtheria were reported in San Francisco during 1948, with 18 deaths in the local series of cases and 1 death in the nonlocal group. This is the highest incidence reported since 1932, when 113 local cases were reported. The death rate for the past year, 2.2 per 100,000 population, is the highest since 1930. The case fatality rate for the year was 19.3. Sex distribution in cases shows 74 per cent males and 26 per cent females. The continued shifting of cases into the older age groups is again evident. More than one half of the cases for the year were in the age groups over 40, with 43 per cent of them in the first three five-year periods. Only 8 per cent of the patients were not hospitalized, and these were for the most part patients who died before hospital care could be provided. In only 12 of the 93 cases was there any history of immunization. With a definite program of immunization operating in the public schools, it is a matter of concern that only about one third of the school and preschool groups definitely stated that immunization had been done. Seven persons were not treated, and 5 of these died. In the local series of cases there were five instances where 2 or more members of a family were ill with diphtheria. In five other instances 2 or more cases not family contacts were found at the same address. It is evident that in San Francisco diphtheria is becoming increasingly a disease of the adult and is not recognized clinically as such soon enough.

## COLORADO

**Cancer Seminar at Colorado Springs.**—The Glockner-Penrose Hospital, Colorado Springs, is sponsoring a cancer seminar to be held at the Broadmoor Hotel September 10. The State Society of Pathologists in Colorado and the regional section of the College of American Pathologists are co-sponsors. The seminar will be conducted by Dr. Arthur P. Stout, Columbia University, New York, and Dr. Lauren V. Ackerman, Washington University, St. Louis. Fifteen cases of histologic problems in the field of tumors will be chosen for discussion. Physicians wishing to present a case problem of histologic diagnosis should send a slide and a short summary of the case to Dr. Juan A. del Regato, director of the hospital. It will be submitted to the guest speakers, who will decide on the cases that are to be presented.

## ILLINOIS

**Maternal Welfare Committee.**—At a meeting June 29 the Joint Maternal Welfare Committee of Cook County elected Drs. Fred L. Adair honorary chairman, Joseph L. Baer chairman and Frank F. Maple co-chairman. This committee has worked closely for more than 10 years with the Chicago Board of Health by assisting in the determination of the rules and regulations for the operation and conduct of hospital maternity departments.

### Chicago

**Dr. Holinger to Lecture in Europe and South America.**—Dr. Paul H. Holinger, associate professor of otolaryngology, University of Illinois College of Medicine, Chicago, left July 7 for a two month speaking tour of Europe and South America. He presented four endoscopic films before the International Congress of Otolaryngology in London and a paper on "Endoscopic Photography in Otolaryngology and Bronchoesophagology" and also gave two lectures in Lisbon, Portugal, July 25 and 26. Dr. Holinger has been invited to serve as honorary president of the Argentine Congress of Bronchoesophagology, which will be held in Sante Fe on August 15 and 16. The Argentine Society of Broncho-Esophagology, through its president, Dr. Irigoyen Freyre, also has invited him to give two courses in bronchoesophagology at the medical school in Sante Fe. While in South America he will lecture at Cordoba, Buenos Aires, Porto Alegre and Rio de Janeiro. He plans to return to the United States in September.

**Michael Reese Hospital Expansion.**—Ground was broken June 27 with ceremonies which marked the launching of construction of Michael Reese Hospital's $1,850,000 Institute for Psychosomatic and Psychiatric Research and Training. The institute will be the second major hospital building to be constructed in the long range enlarged medical center plan of Michael Reese. Also scheduled for early construction are a private pavilion for medical and surgical patients and a convalescent hospital. The Institute for Psychosomatic and Psychiatric Research and Training has been functioning since 1946.

**Cardiovascular Research.**—The Chicago Heart Association on July 1 assigned the following grants totaling $114,300 to local institutions engaged in cardiovascular research: $18,300 to the University of Chicago; $5,000 to the Cardiovascular Research Institute of Michael Reese Hospital; $10,000 to the University of Illinois College of Medicine; $35,000 to the Rheumatic Fever Research Institute of Northwestern University; $10,000 to the Stritch School of Medicine of Loyola University; $25,000 to LaRabida Jackson Park Sanitarium; $10,000 to Herrick House, and $1,000 to cover cost of nose and throat cultures in connection with Dr. Kate Kohn's study of the use of oral penicillin to prevent recurrence of rheumatic fever. The association expects to make additional research grants later in the year from contributions to its 1949 fund drive.

## INDIANA

**Emergency Medical Service.**—A survey by the Indiana State Medical Association has revealed that seventy-five of the eighty-three Indiana county medical societies have established round-the-clock medical service. Of the eight counties which did not report any such arrangement, seven were rural and only one a metropolitan area.

**Immunization Letters to Parents.**—The Madison County Medical Society in cooperation with the Anderson City and the Madison County Health Department is sending a special letter to parents of all babies who have reached their six month birthday. It is a reminder to the parents to see the family physician about the child's immunization and suggests a possible schedule to follow for protection against diphtheria, whooping cough and smallpox.

## IOWA

**Personals.**—Dr. Harold W. Morgan, Mason City, has been awarded a bronze medal in recognition of his services in furthering the cancer control program in Iowa.——Dr. William C. Goenne, Davenport, was elected president of the Iowa Clinical Surgical Society in April.

**Committee to Act as Dean of Medical School.**—Following the recent death of Dr. Mayo H. Soley, dean of the University of Iowa Medical School, President Virgil M. Hancher appointed an executive committee to carry on the administrative functions of the college of medicine. The committee consists of Dr. Robert Tidrick of the department of surgery as chairman, Dr. Willis Fowler of the department of medicine, Dr. Rex Ingram of the department of anatomy, Dr. Emory Warner of the department of pathology and Dr. Wilbur R. Miller of the department of psychiatry. The executive committee is authorized to exercise all of the powers and perform all of the functions of the dean until a permanent dean can be appointed or until a better interim solution can be found.

## KENTUCKY

**Cancermobile.**—The state department of health is to receive from the U. S. Public Health Service $16,240, which will aid in the activities of the Cancermobile, which travels through rural areas of Kentucky to aid in early diagnosis. The $4,950 allotted the University of Louisville School of Dentistry will be used to promote special lectures on cancer and to train junior and senior students to recognize cancerous or precancerous conditions of the mouth and face.

**Personals.**—Dr. Milton Davis Jr., associate professor of anesthesiology at the University of Louisville School of Medicine, has submitted his resignation effective June 30.——Dr. Joseph A. Little has been appointed pediatrics consultant to Dr. Cathryn C. Rotondo of the Maternal and Child Health Division of the Kentucky State Department of Health effective July 1. He plans to put on a state child-health program in cooperation with other divisions of the state health department and will teach pediatrics at the University of Louisville School of Medicine. During World War II he was stationed at Army Air Force hospitals at Randolph Field, Texas, and Hamilton Field, California. Later he was pediatrics resident and director of the outpatient department and instructor in pediatrics at Children's Hospital, Cincinnati.

## MINNESOTA

**Dr. Wangensteen Awarded Prize.**—On July 14 the College of Physicians of Philadelphia awarded the Alvarenga Prize for 1949 to Dr. Owen H. Wangensteen, director of the department of surgery, University of Minnesota Medical School, Minneapolis, for his contributions to the etiology and therapy of gastric and duodenal ulcers. Dr. Wangensteen will deliver the Alvarenga Lecture on this subject at the College of Physicians of Philadelphia on November 2. The Alvarenga Prize was established by the will of Pedro Francisco DaCosta Alvarenga of Lisbon, Portugal, an associate fellow of the College of Physicians of Philadelphia, to be awarded annually by the College of Physicians on the anniversary of the death of the testator, July 14, 1883.

**Alumni Gift to Medical Library.**—The purchase of historical books for the medical library at the University of Minnesota was made possible in July when $3,735 was presented to the Friends of the University of Minnesota Library. This gift of the university's medical school classes of 1922-1923 was raised by a committee headed by Dr. Owen H. Wangensteen, director of the department of surgery at the university, during the 1948 and 1949 campaigns of the Greater University Fund. The friends of the library group will carry out the arrangements for buying these historical medical materials. Erritt W. McDiarmid, Ph.D., university librarian, said that the gift "will be of especial value and significance because it will enable the library to acquire some of the outstanding books in the history of medicine that it normally could not purchase with current heavy demand for journals, monographs and other medical materials."

## MONTANA

**Society News.**—The Montana Academy of Eye, Ear, Nose and Throat Specialists elected Dr. James H. Herring, Lewistown, as president, and Dr. Fritz D. Hurd, Great Falls, as secretary-treasurer.

**State Board of Health.**—Dr. Edward S. Murphy of Missoula was elected president of the Montana Board of Health July 1. The 1949 state legislature completely reorganized the health department, voting that its membership should consist of three doctors, a dentist and three laymen. The board formerly was composed of five doctors, a state pharmacy board representative and one member of the state food distribution association. Other physicians on the board are Dr. Brownlow C. Farrand, Jordan, and Dr. Burton K. Kilbourne, Helena, executive secretary.

## OHIO

**Cleveland Health Museum.**—The Veterans' Administration has renewed its contract with the Cleveland Health Museum for "Research in Development of Three-Dimensional Anatomical Models," as requested by Dr. Paul B. Magnuson, chief, medical director, Veterans' Administration. Work is being done in the Health Museum studios with the cooperation of Drs. Normand L. Hoerr and Carl C. Francis, department of anatomy, Western Reserve University School of Medicine, Cleveland.

## PENNSYLVANIA

**New General Hospital.**—The new Ohio Valley General Hospital, built by local residents at a cost of over a million dollars, opened June 27 in McKees Rocks. The hospital has a capacity of 135 beds and 35 bassinets. The old building, which has served the residents since 1900, will be abandoned for hospital purposes. The hospital will serve McKees Rocks, Stowe and Kennedy townships, all of which joined in raising money for the building.

**Anesthesiologists Meeting.**—The Pennsylvania State Society of Anesthesiologists will hold its annual meeting at the William Penn Hotel, Pittsburgh, September 29-October 1. Among the guest speakers are: Lloyd H. Mousel, Washington, D. C., "Pre-operative Preparation and Choice of Anesthetic Agents," and Henry K. Beecher, Boston, "Acidosis and Anesthesia." On September 30 members of the U. S. Bureau of Mines will discuss combustible anesthetic agents and their control. A panel discussion on pediatric anesthesia will take place aturday morning with Drs. Charles H. Robson, Toronto, anada; William O. McQuiston, Peoria, Ill., and James E. kenhoff, Philadelphia, participating.

**Veteran Physicians Honored.**—Four physicians who have completed fifty years of medical service were honored by their colleagues July 21 at the annual meeting of the Eleventh Councilor District of the Medical Society of the State of Pennsylvania at the Somerset Country Club. Dr. E. R. Roger Samuel, Mount Carmel, president-elect of the state medical society, presented fifty year awards to Drs. William A. Prideaux, Twin Rocks; J. French Kerr, Connellsville; Lewis N. Reichard, Brownsville, and Audley O. Hindman, Burgettstown. Dr. David L. McCarrell, of Hickory, who died last March, had also practiced fifty years. Dr. Thomas J. O'Neill, of Hahnemann Medical College and Hospital of Philadelphia, and Dr. Robert C. Grauer, of the University of Pittsburgh, were visiting speakers. Mr. Lester H. Perry, Harrisburg, executive secretary of the state society, and Mr. Leo E. Brown, Harrisburg, of the Committee on Public Relations of the state society, spoke on the campaign against socialized medicine.

### Philadelphia

**Personal.**—On June 7 William N. Parkinson, dean, Temple University Medical School and Hospital, was awarded the honorary degree of Doctor of Science by the Pennsylvania Military College, Chester, Pa.

**Gift to Temple University.**—Dr. Theodore L. Chase of Reno, Nev., who contributed $1,000,000 to establish the Agnes Barr Chase Surgical Research Foundation in memory of his wife, has made an additional gift of $400,000 for the new building to be erected at the Temple University Medical Center.

**Bequest for Medical Research.**—In the will of the late A. Atwater Kent, philanthropist and retired radio manufacturer, the University of Pennsylvania School of Medicine and Jefferson Medical College, Philadelphia, will each receive $250,000 for medical research. The gifts, to be held in trust, are to be paid each institution annually until the funds are exhausted.

**Gabriel Tucker Fund for Research.**—A patient who underwent successful surgery at the University of Pennsylvania's Graduate School of Medicine has made a gift anonymously to the university of $200,000, the proceeds of which are to be used for the advancement of medicial science. It will be known as "The Gabriel Tucker Fund for Bronchology, Esophagology and Laryngeal Surgery."

**Samuel D. Gross Essay Prize.**—The Philadelphia Academy of Surgery will present its Samuel D. Gross essay prize of $1,500 in 1950. The prize is awarded every five years to the writer of the best original essay on a subject in surgical pathology or surgical practice founded on original investigations, the candidates for the prize to be American citizens. The competitor who receives the prize must publish his essay in book form. The essay must be written by a single American citizen and sent to the "Trustees of the Samuel D. Gross Prize of the Philadelphia Academy of Surgery, care of the College of Physicians, 19 South 22nd Street, Philadelphia," on or before Jan. 1, 1950. Each essay must be typewritten, distinguished by a motto and accompanied by a sealed envelope bearing the same motto, containing the name and address of the writer. No envelop will be opened except that which accompanies the successful essay. The committee reserves the right to make no award if the essays submitted are not considered worthy of the prize.

## TEXAS

**Dr. Sunderman to Head Clinical Pathology Department.**—Dr. F. William Sunderman, physician, educator and research worker, has assumed duties as director of clinical research and head of the department of clinical pathology at the University of Texas' M. D. Anderson Hospital for Cancer Research, Houston; in addition, he has been appointed professor of experimental medicine and clinical pathology at the University of Texas Postgraduate School of Medicine. Dr. Sunderman came to Houston from Cleveland, where he was head of the department of clinical pathology at the Cleveland Clinic Foundation. Dr. Sunderman is currently vice president of the American Board of Pathology. For services rendered during World War II he received the Naval Ordnance Development Award and a War Department and Navy Department citation.

## WASHINGTON

**Personal.**—The Pacific Northwest Dermatological Society, meeting in Seattle in May, installed Dr. Robert L. Howard, Spokane, as president.

**Graduate Course in Obstetrics and Pediatrics.**—The Washington State Medical Association, the State Department of Health and the School of Medicine of the University of Washington will present postgraduate courses in obstetrics and pediatrics at King County Hospital in Seattle, August 8-12. The registration fee, $25, should be sent to the Washington State Medical Association, 338 White-Henry-Stuart Building, Seattle 1.

## WEST VIRGINIA

**Hospitals Licensed.**—At the end of the first year of operation under the state's new hospital-licensing law, 86 hospitals in West Virginia have been approved and are operating under licenses granted by the state health department. Of this number 69 are general hospitals, 9 eye, ear, nose and throat, 4 orthopedic, 2 tuberculosis, 1 maternity and 1 chronic disease hospital. In addition to the hospitals, licenses have been granted to 5 clinics and 22 nursing homes.

**Heart Disease Clinic for Indigents.**—A diagnostic clinic for indigents suffering from cardiovascular diseases has been established in Charleston by the West Virginia Heart Association. The clinic meets each Tuesday at noon in the Kanawha-Charleston health department, and patients are seen by appointment. A similar clinic is operating in Wheeling. Plans are under way to use equipment of the rheumatic fever project of the state health department in Fairmont to expand diagnostic services in northern West Virginia to all age groups. Another diagnostic clinic is also planned for Huntington.

**Occupational Disease Board.**—An occupational disease medical board has been appointed by Curtis B. Trent Jr., compensation commissioner, under the provisions of a bill amending the Workmen's Compensation Act, passed at the regular session of the 1949 Legislature. The board will be composed of Dr. John C. Condry of Charleston, chairman, who will serve a one year term, and Dr. James L. Patterson of Logan, who is appointed for a three year term. Subsequent appointments to the board will be for full three year terms. The members of the board took office July 1, and an organization was to be set up at a meeting scheduled for July 21. Under the amended act the coverage of Workmen's Compensation is extended to all occupational diseases. The old law provided coverage for only silicosis and accidental injuries.

## GENERAL

**Award Osler Medal.**—The American Association of the History of Medicine at its annual meeting held in Lexington, Ky., May 22-24, awarded the William Osler Medal to Mr. Charles Van Arsdall, a fourth year student at Johns Hopkins University School of Medicine, Baltimore, in recognition of his essay on "A Medical History of the Harrodsburg Springs."

**Vitamin Foundation Grants.**—Six new grants-in-aid have been announced by the National Vitamin Foundation for research on the effects and significance of vitamins to health and resistance to disease. The awards bring to $190,828 the financial aid extended to scientists and institutions by this nonprofit, research organization supported by leading chemical and pharmaceutic concerns.

**Biological Photographic Association.** — The nineteenth annual meeting of the Biological Photographic Association, Inc., will be held in Cleveland, September 7-10, at the Hotel Cleveland. The preliminary agenda calls for one afternoon to be spent at Nela Park, the research laboratories of General Electric and the home of Horizon House, where the latest in lighting will be demonstrated.

**Personals.**—Dr. Paul M. Wood, New York, resigned January 1 as president of the American Board of Anesthesiology and was succeeded by Dr. Charles F. McCuskey, Los Angeles. ——The Board of Scientific Directors of the Rockefeller Institute for Medical Research has announced that Walter A. Jacobs, Ph.D., New York, and Louis O. Kunkel, Ph.D., Princeton, N. J., who have reached the age of retirement, have been made members emeriti of the institute.

**Joins Tuberculosis Association Staff.**—Dr. Floyd M. Feldmann, Washington, D. C., will join the staff of the National Tuberculosis Association this summer as assistant to the managing director, Dr. James E. Perkins, Bronxville, N. Y. Dr. Feldmann is medical director, central Coordination and Analysis Office, and executive secretary, Tuberculosis Study Section, U. S. Public Health Service. He has been epidemiologist for the Minnesota Department of Health.

**Nineteen Fellowship Awards.**—The National Research Council has announced the award of nineteen fellowships in the medical sciences. These fellowships are supported by an appropriation of the Rockefeller Foundation and are designed to give special facilities for training in research to persons who wish to devote themselves to an investigative career in the medical sciences. Such awards are intended for recent graduates who are not professionally established.

**Tuberculosis Academy Awards.**—At the annual meeting of the American Academy of Tuberculosis Physicians in Atlantic City, June 4, gold keys were awarded to Drs. Robert A. Peers, Colfax, Calif.; Charles F. Taylor, Norton, Kan., and Zoltan Galambos, Chicago. In addition, a certificate was presented to Dr. Camille Kereszturi Cayley, New York, honoring her for her pioneer work in BCG vaccination.

**American Board of Obstetrics and Gynecology.**—The annual meeting of the American Board of Obstetrics and Gynecology was held in Chicago May 8-14, at which time 236 candidates were certified. The next scheduled examination (Part I), written examination and review of case histories, for all candidates will be held in various cities of the United States and Canada on Feb. 3, 1950. Application may be made until November 5. Application forms are sent on request to the board, 1015 Highland Building, Pittsburgh 6, Pa.

**Prevalence of Poliomyelitis.**—Reports of cases of poliomyelitis for the periods indicated have been received from the Division of Public Health Methods, U. S. Public Health Service:

| | Week Ended | | | Total to | | Total * | |

* Last two columns show reported incidence since approximate average seasonal low: 17 weeks.

† Figures changed by corrected reports.

‡ Correction: New Jersey, week ended May 7, 3 cases instead of 5.

**Smallpox in the United States.**—The June issue of the *Statistical Bulletin* of the Metropolitan Life Insurance Company reports that 59 cases of smallpox were reported in the United States in 1948, a new low record; 14,939 were reported in the United States in 1938. In 1948, 27 states and the District of Columbia were entirely free from smallpox. The reduction of smallpox cases in 1948 is not continuing in 1949. Through May there were 49 cases this year as compared with 45 in the like period of 1948. Missouri and Texas each reported 8 cases and Kansas and Mississippi 5 each.

**Occupational Therapy Consultant.**—Frances Helmig, director of the Rochester (N. Y.) Rehabilitation Center, has been appointed occupational therapy consultant for the National Society for Crippled Children and Adults effective July 1. The society has more than 2,000 state and local affiliated units and more than 80 centers specializing in cerebral palsy, in addition to other services for the handicapped. Miss Helmig will act as consultant to these units in developing further services. She also has served as head of the Occupational Therapy Department of the Naval hospital at Philadelphia.

**Southern Anesthesiologists Organize.**—At an organization meeting in Washington, D. C., April 8, the Southern Society of American Anesthesiologists was formed. It includes the territory east of the Mississippi and south of the Mason-Dixon Line, plus Missouri, Arkansas, Oklahoma and Texas. Officers elected were Drs. Perry P. Volpitto, Augusta, Ga., president; Harvey C. Slocum, Galveston, Texas, president-elect, and John Adriani, New Orleans, secretary. The group will meet each year in conjunction with the Southern Medical Association. At the same meeting, the old Southeastern Section of the American Society of Anesthesiologists was disbanded.

**Coulee Dam Needs Two Doctors.**—The U. S. Bureau of Reclamation is seeking two doctors for the Grand Coulee Dam Area in eastern Washington—population about 7,500. General practitioners with special interests in internal medicine, surgery, pediatrics or obstetrics are needed. The bureau has a building in Coulee Dam with about 1,200 square feet of space available to doctors. The government will contribute up to $15,000 toward the cost of remodeling the building into offices as desired by the new tenants. Bids from two doctors will be opened September 15. Housing will be made available. For details write to the District Manager, United States Bureau of Reclamation, Coulee Dam, Washington.

**Mississippi Valley Essay Contest.**—Dr. Seymour H. Rinzler, adjunct in medicine and cardiology, Beth Israel Hospital, New York, and instructor in rehabilitation, New York University, is the winner of the annual essay contest of the Mississippi Valley Medical Society "for the best unpublished essay on a subject of practical and applicable value to the general practitioner of medicine." Dr. Rinzler's paper is entitled, "Present Status of Medical and Surgical Therapy in Angina Pectoris." Second prize goes to Dr. Edward D. Robbins of the University of Chicago for his essay "Hypometabolism on Hypothyroidism," and third prize to Dr. Wallis L. Craddock, Ft. Logan, Colo., for his paper "The Problem of Histoplasmosis." Dr. Rinzler will receive a cash award and a gold medal and will present his essay at the annual meeting of the society in St. Louis, September 28-30.

**Medical Personnel for Relief Projects.**—The American Friends Service Committee is interested in recruiting qualified medical personnel for its relief projects in Palestine and China. All traveling and maintenance expenses are provided, but no salaries are paid to overseas workers. The Quakers are administering relief to some 250,000 Arab refugees in Southern Palestine. Its public health program under the direction of Dr. Jerome Peterson, on loan from the World Health Organization, consists of medical and surgical work in clinics and hospitals, maternity and child welfare services and epidemic prevention and control. Of the 50 field workers of the committee in the Gaza area, 15 are medical personnel. Palestine appointments will last through Dec. 31, 1949. In China Quaker medical work is of an emergency nature, treating both civilian and army war casualties and combating epidemics. The minimum term of service is two years. Doctors interested should write Charles Read, American Friends Service Committee, 20 South Twelfth Street, Philadelphia 7, Pa.

**Congress of Otorhinolaryngology and Bronchoesophagology.**—This second Pan American congress will meet in Montevideo and Buenos Aires Jan. 8-15, 1950. At Montevideo, January 8-14, the sessions will deal with the following subjects: Frontal Sinus; Tumors of Pharynx; Buco-pharyngeal and Laryngeal Lesions Caused by Fungi or Parasites; Treatment of Cancer of the Larynx; Bronchial Obstruction in Children, and Benign Disease of the Esophagus. Three simultaneous courses will be given during the afternoon on: nose and sinuses, pharynx and larynx and bronchoesophagology. Sessions at Buenos Aires January 13-14, during the afternoons, will take up word hearing; acuophone and acuometer, and otosclerosis. Simultaneous courses will be given on inflammatory infections of the ear and their complications, and otosclerosis. The subscription is $10 or its equivalent in Uruguayan money. The week following the courses, January 16-21, operative demonstrations will take place in Montevideo and Buenos Aires. All interested should communicate at once with the delegate in the United States and Canada, Dr. Chevalier L. Jackson, 3401 North Broad Street, Philadelphia 40, Pa.

**National Foundation Scholarships and Fellowships.**—The National Foundation for Infantile Paralysis will continue to award scholarships and fellowships in physical medicine, public health, medical social work and physical therapy under recently approved appropriations totaling $495,000. A limited number of clinical fellowships in physical medicine are available to physicians who wish to prepare for eligibility for certification by the American Board of Physical Medicine. The fellowships, for which $100,000 has been allocated, will cover a period of one, two or three years of clinical study, depending on individual needs. Fellowships are available to physicians for one year of graduate study leading to the degree of Master of Public Health. This study requires one year at a school of public health approved by the American Public Health Association; $50,000 has been set aside for this project. Physical therapy scholarships are available to men and women who need financial assistance to complete training in schools approved by the Council on Medical Education and Hospitals of the American Medical Association; $225,000 has been provided for this purpose. Medical social work scholarships are available to students accepted as degree candidates by an accredited school of social work. Also available are a number of scholarships for students who need more than a year of graduate study to receive a Master's degree in medical social work; $100,000 will finance this project. Fellowships of two to four weeks' duration are also being offered to about fifty residents in orthopedics and pediatrics to study treatment of patients with poliomyelitis in courses to be given at Children's Hospital in Boston, City Hospital in Cleveland, University of Colorado Medical Center in Denver and Stanford University School of Medicine in San Francisco; $20,000 has been provided for this training. All scholarships and fellowships are awarded on the recommendations of a committee and are on a competitive basis. Information may be obtained from the Division of Professional Education, National Foundation for Infantile Paralysis, 120 Broadway, New York 5, N. Y.

## FOREIGN

**Dr. Trueta Appointed Nuffield Professor.**—Dr. Josep Trueta, surgeon at the Wingfield Morris Orthopaedic Hospital in Oxford, England, since 1941, has been appointed Nuffield Professor of Orthopaedic Surgery at the University of Oxford. Dr. Trueta was educated at Barcelona Institute and University.

**Symposium of Neutroadiologicum.**—This symposium meeting in Rotterdam September 13-17 will deal with skull roentgenology, arteriography, encephalography, ventriculography and myelography. Those who wish to participate should send their names not later than July 31 to the Secretary of the Symposium Neuro-radiologicum, Rotterdam (Holland), who can also furnish all information.

## CORRECTION

**Personal.**—Dr. Francis C. Lowell, associate professor of medicine at Boston University School of Medicine, has been appointed assistant dean at the university, and not at Harvard Medical School as was stated in The Journal July 16, page 967.

# Marriages

Catherine Burkhart to Mr. Robert D. McAuliffe, both of Syracuse, N. Y., April 21.

John Joyce Sayen, Wynnewood, Pa., to Miss Anne Elizabeth Read of Bryn Mawr, May 21.

Bernard Drexler to Miss Bessie Poze, both of Rochester, N. Y., at Miami, Fla., April 11.

Robert C. Waltz, East Cleveland, Ohio, to Miss Frances Elaine Woosley of London, June 1.

# Deaths

**Ralph Pemberton** ⊕ charter member of the Council on Physical Therapy of the American Medical Association, died at his home in Paoli, Pa., June 17, aged 71, of coronary occlusion. Dr. Pemberton was born in Philadelphia Sept. 14, 1877. He was educated at the University of Pennsylvania, where he also received his degree in medicine in 1903. Later he studied in Berlin and at the University of Strasbourg. In 1905 he began practice in Philadelphia and became an instructor in medicine at his alma mater, serving from 1907 to 1910. In 1928 he was made an associate professor of medicine and in 1931 professor at the Graduate School of Medicine, University of Pennsylvania. He was president of the Ligue Internationale Contre le Rhumatisme and since 1944 of the Pan-American League for the Study and Control of Rheumatic Diseases. From 1927 to 1935 he was chairman of the American Committee for Control of Rheumatism and in 1938-1939 president of the American Rheumatism Association. He was a fellow of the American College of Physicians and the College of Physicians of Philadelphia and a member of the American Institute of Nutrition, the Academy of Natural Sciences, International Society of Medical Hydrology, the Military Order of the Loyal Legion of the United States, American Society for Clinical Investigation and the American Academy of Physical Medicine, which in 1946 awarded him the gold key. In 1939 he was presented the Meritorious Service Medal by the Commonwealth of Pennsylvania. He was an honorary fellow of the Royal Society of Medicine in London and an honorary member of various medical societies throughout the world. During World War I Dr. Pemberton served as a major in the medical corps of the U. S. Army. He has been national consultant in rheumatism and arthritis under the program of Wartime Graduate Medicine Meetings since 1943 and chairman of the Philadelphia Department of Health's committee on rheumatic diseases since 1944. He was a specialist certified by the American Board of Internal Medicine and at various times associated with the University, Presbyterian, Philadelphia General, Abington (Pa.) Memorial and Chester (Pa.) hospitals. Dr. Pemberton wrote "Arthritis and Rheumatoid Conditions," a volume translated into French. With Dr. Robert B. Osgood, he wrote "Medical and Orthopedic Management of Chronic Arthritis." Besides being a contributor to other books and journals, he was an editor of a volume on "Principles and Practice of Physical Therapy."

**Charles Johnstone Imperatori** ⊕ Essex, N. Y.; born in New York Jan. 20, 1878; University and Bellevue Hospital Medical College, New York, 1899; specialist certified by the American Board of Otolaryngology; formerly professor of laryngology at the New York Post-Graduate Medical School and Hospital in New York and professor of otorhinolaryngology at his alma mater; fellow of the American Academy of Ophthalmology and Otolaryngology, American College of Surgeons, of which he was a member of the board of governors from 1942 to 1944, and the New York Academy of Medicine; past president of the American Bronchoscopic Society; past president and secretary of the American Laryngological Association; member of the American Laryngological, Rhinological and Otological Society; lieutenant colonel during World War I, serving in France as commanding officer of the 309th medical regiment, American Expeditionary Forces; for his services France decorated him with the Medaille D'Honneur Des Epidemies; during World War II a member of the division of medical sciences of the National Research Council; affiliated with Flower-Fifth Avenue, Manhattan Eye, Ear and Throat and Riker's Island hospitals in New York; consulting laryngologist at the Harlem Hospital in New York and Nyack (N. Y.) General Hospital; with Dr. H. J. Burman, author of "Diseases of Nose and Throat"; died June 15, aged 71.

**Mayo Hamilton Soley** ⊕ Iowa City; born in Malden, Mass., April 14, 1907; Harvard Medical School, Boston, 1933; interned at Massachusetts General Hospital in Boston; since 1948 dean and research professor in the department of internal medicine at the State University of Iowa College of Medicine; formerly professor of medicine and assistant dean at the University of California Medical School in San Francisco, where he was on the staffs of the University of California, San Francisco City and County and the Letterman General hospitals; member of the American Society for Clinical Investigation, Association for the Study of Internal Secretions, American Heart Association and the Society for Experimental Biology and Medicine; specialist certified by the American Board of Internal Medicine; certified by the National Board of Medical Examiners; director of medical services of the University Hospitals; died June 21, aged 42.

**George Alfred Skinner** ⊕ Colonel, U. S. Army, retired, Berkeley, Calif.; born in Osage, Iowa, June 11, 1870; Rush Medical College, Chicago, 1892; entered the medical corps of the U. S. Army in 1896; served during the Spanish-American War and World War I; chief medical officer in the Seventh Corps area in Omaha when he retired on June 30, 1934; in 1931 was awarded the Henry S. Wellcome medal and prize of $500 for an essay on sanitation; professor emeritus of public health at the University or Nebraska College of Medicine in Omaha; fellow of the American College of Surgeons and the American College of Physicians; died in Letterman General Hospital, San Francisco, May 15, aged 78, of coronary thrombosis.

**Achille Frank Baratta** ⊕ New York; Tulane University of Louisiana School of Medicine, New Orleans, 1921; affiliated with the Morrisania City Hospital; died May 12, aged 52.

**Leroy Becker** ⊕ Cobleskill, N. Y.; Albany Medical College, 1892; served as county coroner; died April 28, aged 80, of coronary occlusion.

**Salvator Benanti,** Brooklyn; Long Island College Hospital, Brooklyn, 1910; died May 20, aged 73.

**John Thomas Bradshaw** ⊕ Dade City, Fla.; St. Louis University School of Medicine, 1904; past president of the Paso, Hernando and Citrus Counties Medical Society; served during World War I; died in Zephyrhills May 22, aged 78, of coronary thrombosis.

**Harold Welch Brann,** Palo Alto, Calif.; St. Louis University School of Medicine, 1906; member of the American Psychiatric Association; affiliated with Veterans Administration hospitals in various cities; died April 9, aged 64.

**Frederick Watson Buckley** ⊕ Beatrice, Neb.; Northwestern University Medical School, Chicago, 1907; an Associate Fellow of the American Medical Association; for many years secretary of the Gage County Medical Society; a past vice president of the Nebraska State Medical Association; served during World War I; member of the American Association of Railroad Surgeons; died April 23, aged 68.

**Albert Ewing Childs,** Stanfield, Ore.; New York University Medical College, New York, 1896; formerly health officer of Bantam and Morris in Connecticut; died April 12, aged 76, of arteriosclerosis.

**Orra Fernando Covert,** Moundsville, W. Va.; Rush Medical College, Chicago, 1901; member of the American Medical Association and in 1909 a member of its House of Delegates; past president of the Marshall County Medical Society and the West Virginia Tuberculosis and Health Association; for many years on the staff of Reynolds Memorial Hospital in Glen Dale; died May 26, aged 84, of arteriosclerosis.

**Harriet Jean Bower Farnham,** Glendale, Calif.; University of Minnesota Medical School, Minneapolis, 1923; assistant clinical professor of pediatrics at the College of Medical Evangelists, Loma Linda and Los Angeles; affiliated with Los Angeles General Hospital, Glendale Sanitarium and Physicians and Surgeons Hospital, where she died April 4, aged 50, of carcinoma of the right breast.

**Albert Ferdinand Garton,** Philadelphia; Medico-Chirurgical College of Philadelphia, 1904; member of the American Medical Association; died April 15, aged 68.

**Harold Girard Giddings,** Boston; Harvard Medical School, Boston, 1907; member of the American Medical Association; past president of the Middlesex South District Medical Society; fellow of the American College of Surgeons; served during World War I; on the staffs of Whidden Memorial Hospital in Everett, Massachusetts General Hospital, Boston, and the Newton-Wellesley Hospital in Newton, where he died May 28, aged 69, of coronary occlusion.

**Frederic Wilhelm Hall,** Ponca City, Okla.; University of Kansas School of Medicine, Kansas City, 1936; member of the American Medical Association and the Kansas State Medical Society; specialist certified by the American Board of Internal Medicine; served during World War II; formerly on the staffs of William Newton Memorial Hospital and St. Mary's Hospital in Winfield, Kan.; died May 20, aged 37, of meningitis.

**Frederick Spencer Hallett** ⊕ Hackensack, N. J.; Long Island College Hospital, Brooklyn, 1893; for many years county jail physician; formerly member of the city board of health; served on the staff of the Hackensack Hospital; died May 18, aged 78, of arteriosclerotic heart disease.

**Silas F. Hallock** ⊕ New York; Western Reserve University Medical Department, Cleveland, 1885; served on the staff of the Manhattan Eye, Ear and Throat Hospital; died April 24, aged 87, of heart disease.

**Samuel Terrell Hardin,** Tuscaloosa, Ala.; University of Alabama School of Medicine, 1914; member of the American Medical Association; member of the city and county health departments; physician for city, county and federal prisoners; for many years county coroner; affiliated with the Druid City Hospital, where he was president of the staff; died May 16, aged 72, of coronary thrombosis.

**Albert Michael Healey,** New York; University and Bellevue Hospital Medical College, New York, 1907; died in St. Joseph's Hospital, Yonkers, June 11, aged 67, of cerebral hemorrhage.

**Evelyn Helman,** Santa Rosa, Calif.; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1899; died April 25, aged 82, of carcinoma of the large intestine.

**Edward Robert Henning,** Bellefontaine, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1898; for many years county coroner; for twenty-five years surgeon for the New York Central Railroad; died May 31, aged 78, of uremia.

**Frances Houston,** Whitefish, Mont.; Rush Medical College, Chicago, 1916; formerly physician to women at the University of Washington in Seattle; died May 22, aged 62, of thrombosis.

**Albert Victor Keebler,** Lake Worth, Fla.; University of Louisville (Ky.) Medical Department, 1910; died in the Veterans Administration Hospital in Coral Gables April 21, aged 62.

**Raymond Miles Krepps,** Philadelphia; Tufts College Medical School, Boston, 1917; served as industrial physician for Sharp & Dohme, Inc.; died May 12, aged 58, of coronary occlusion and myocardial infarction.

**Owen William Krueger** ⊕ Kansas City, Mo.; Kansas City Medical College, 1890; fellow of the American College of Surgeons; affiliated with St. Margaret's Hospital in Kansas City, Kan.; died May 20, aged 84, of embolism, cardiorenal disease and auricular fibrillation.

**Alexander Leon Louria** ⊕ Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1913; on the faculty of the Long Island College of Medicine; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; a director of the American Jewish Physicians' Committee; affiliated with Jewish Hospital, where he died May 22, aged 59, of carcinoma of the lung with cerebral metastases.

**James Gregory McNeil,** Chicago; Loyola University School of Medicine, Chicago, 1921; member of the American Medical Association; on the staff of the South Chicago Community Hospital, died in Albuquerque, N. Mex., May 19, aged 56, of carcinoma of the throat.

**Moss Maxey,** Mount Vernon, Ill.; Missouri Medical College, St. Louis, 1897; member of the American Trudeau Society; died June 13, aged 75, of cardiorenal disease and arteriosclerosis.

**Harry Hampton Mayo,** Martin, Ky.; University of Louisville Medical Department, 1914; served during World War I; died in the Veterans Administration Hospital, Lexington, May 10, aged 61, of coronary occlusion.

**Lamar Cecil Oyster,** Clarksburg, W. Va.; Baltimore Medical College, 1901; died in the U. S. Marine Hospital, Staten Island, N. Y., May 17, aged 75, of generalized carcinomatosis.

**Roy Lee Page,** Tyler, Texas; University of Louisville (Ky.) Medical Department, 1909; member of the American Medical Association; died May 7, aged 64, of coronary occlusion.

**Otto S. Pavlik** ⊕ Oak Park, Ill.; Northwestern University Medical School, Chicago, 1904; formerly assistant professor of gynecology at his alma mater; member of the Central Association of Obstetricians and Gynecologists; affiliated with Wesley Memorial Hospital in Chicago and West Suburban Hospital; died March 29, aged 74, of coronary thrombosis.

**Walter Charles Popp** ⊕ Rochester, Minn.; University of Pittsburgh School of Medicine, 1929; assistant professor of radiology at the University of Minnesota Graduate School; specialist certified by the American Board of Radiology; member of the Radiological Society of North America; affiliated with the Mayo Clinic; died June 4, aged 48, of myocardial infarction and coronary sclerosis.

**William Landacre Pritchard** ⊕ Hilliards, Ohio; Ohio State University College of Medicine, Columbus, 1933; for many years president of the village school board; on the staff of the Mount Carmel Hospital, Columbus, where he died May 21, aged 43, of a ruptured sigmoid colon.

**William Rennie** ⊕ Buffalo; born in Pittsburgh on Dec. 1, 1893; University of Buffalo School of Medicine, 1920; served overseas during World War II with the 21st Field Hospital, rising from rank of captain to major; won the Bronze Star for "meritorious service" as head of a military hospital at Chungking, China, as well as a citation from the Republic of China; service terminated in March 1946; city diagnostician for Buffalo and county diagnostician for Erie County; died May 16, aged 55, of hypertensive heart disease.

**Frank D. Rowell,** Gilbert, Ariz.; University Medical College of Kansas City, Mo., 1897; died in the South Side District Hospital, Mesa, April 20, aged 79, of chronic nephritis and arteriosclerosis.

**Alfred Stephan Sigmann,** Bellevue, Pa.; Medizinische Fakultät der Universität, Wien, Austria, 1897; member of the American Medical Association; served on the staff of St. John's Hospital in Pittsburgh; died May 7, aged 81, of lymphosarcomatosis.

**Silas Sinclair Snider** ⊕ Chicago; Rush Medical College, Chicago, 1934; specialist certified by the American Board of Pediatrics; for many years pathologist for the county coroner's office; on the staff of St. Luke's Hospital; killed June 15, aged 41, when the monoplane in which he was flying crashed.

**William Jenness Sparhawk,** Cape Girardeau, Mo.; Barnes Medical College, St. Louis, 1903; member of the American Medical Association; affiliated with St. Francis and Southeast Missouri hospitals; died April 25, aged 69, of coronary disease.

**Charles Francis Spencer,** Ossining, N. Y.; University of the City of New York Medical Department, New York, 1882; formerly chief inspector of contagious diseases, health department of the city of New York; died May 23, aged 92, of heart disease.

**Joseph Marion Stallcup,** Cleburne, Texas (licensed in Texas, under the Act of 1907); past president of the Johnson County Medical Society; city health officer; died May 13, aged 75, of coronary occlusion.

**Ernest Richard Stoehr,** San Francisco; Rush Medical College, Chicago, 1932; died in May, aged 43, as the result of injuries received in an automobile accident.

**George W. C. Studley,** South Portland, Me.; Medical School of Maine, Portland, 1904; at one time health commissioner; died in the Veterans Administration Hospital, Togus, April 19, aged 74.

**Ernest Albert Taylor,** West Burke, Vt.; University of Vermont College of Medicine, Burlington, 1904; died in the Brightlook Hospital, St. Johnsbury, April 14, aged 77.

**Edwin G. Thompson,** Providence, R. I.; Medico-Chirurgical College of Philadelphia, 1893; also a graduate in dentistry; member of the American Medical Association; served as physician for the Prudential Life Insurance and Metropolitan Life Insurance companies; on the staff of the Roger Williams General Hospital; died May 11, aged 84, of carcinoma of the rectum.

**Thomas Graham Torpy,** Minocqua, Wis.; Rush Medical College, Chicago, 1895; member of the American Medical Association; died in Sacred Heart Hospital, Tomahawk, May 31, aged 80, of cardiac insufficiency and severe secondary anemia.

**Charles Frederick Vasey,** Cleveland Heights, Ohio; Jefferson Medical College of Philadelphia, 1901; died in Lakeside Hospital, Cleveland, May 16, aged 72, of adenocarcinoma of the colon.

**Miles Abernathy Watkins,** Birmingham, Ala.; Medical Department of Tulane University of Louisiana, New Orleans, 1909; member of the American Medical Association; served during World War I; on the staffs of St. Vincent's, Jefferson and Highland Baptist hospitals; died May 22, aged 63, of coronary thrombosis.

**Israel Irving Weiner,** Brooklyn; New York Homeopathic Medical College and Flower Hospital, New York, 1923; member of the American Medical Association; affiliated with the Veterans Administration; died in Jewish Hospital April 10, aged 50, of diaphragmatic hernia.

**John Frank West,** Belvidere, Ill.; Chicago College of Medicine and Surgery, 1910; member of the American Medical Association; served during World Wars I and II; rating specialist for the medical administration regional office at Louisville, Ky.; died April 28, aged 68, of bronchiectasis, myocarditis and arteriosclerosis.

**Frank S. Wiley,** Fond du Lac, Wis.; Rush Medical College, Chicago, 1883; member of the American Medical Association; fellow of the American College of Surgeons; served on the staff St. Agnes Hospital; died April 12, aged 87.

July 6, 1949.

### Tuberculosis in the Fighting Services

Recruits who enter the Norwegian Navy, Army and Air Force undergo a thorough medical examination, which includes tuberculin testing and, in many cases, a roentgenographic examination. Men with tuberculosis are rejected for service. One therefore might expect the fighting services to be free of tuberculosis, but, unfortunately, they are not. Dr. Martin Seip has concluded from a study of the 1948 class of recruits and of the budget year 1947-1948 that tuberculosis is now the greatest danger to life and health for the three services in peace time. In this budget year 42 per cent of those in the fighting services with a disability requiring financial aid had tuberculosis. The incidence of tuberculosis was three times greater in the Navy than in the Army or Air Force, probably because of the relatively close contacts among the men when at sea. Dr. Seip believes that if the new law for compulsory BCG vaccination could be enforced, many men found to be tuberculin-negative on entering the fighting services could be protected effectively from tuberculosis.

### Housing of Country Doctors

Rural areas in Norway are served by physicians who are appointed as medical officers of health and who also act as private practitioners, thereby supplementing their fixed pay. In view of their official status, these doctors should be provided with proper housing by their employers, the central and local authorities, but often, when an appointment is to be made in some outlying district, the applicant visits the locality and finds that the local authorities have done little or nothing to house him properly. He asks leave of the central authority to remain at his original job. When, as often happens, such leave is given, the vacancy in the district again must be advertised. The Norwegian Medical Association has urged the central authority to require local authorities to build new houses or repair old houses for the incoming doctor.

### Compulsory Drafting of Civilian Doctors

The provisional law of April 18, 1947, empowering the central authority to impose certain medical tasks on civilian doctors, was originally intended to be in force to May 1, 1948. Then it was extended to May 1, 1949. Now the government wants to enforce it until May 1, 1952, in spite of protests from the Norwegian Medical Association, which has expressed fears that the exercise of such powers may cause the authorities to delay considering various reforms in the public health services advocated by the Norwegian Medical Association. If the director of health is to be permitted to order civilian doctors to districts where epidemics or other medical catastrophes have occurred, the Norwegian Medical Association urges that better terms should be provided for these doctors, for example, higher pay, better housing and recognition of such medical service as a factor in future promotions.

### Studies Abroad by Norwegian Doctors

The dollar exchange is stopping study visits to the United States by young Norwegian doctors who wish to specialize and enlarge their medical horizons in a country which is more and more coming to be regarded as the Mecca of medicine. Dollar credits are controlled by the authorities in Oslo and those desiring dollars for a stay in the United States must give cogent reasons for their travel.

## ISRAEL

*(From Our Regular Correspondent)*

JERUSALEM, June 21, 1949.

### Microbiologists' Meeting in Jerusalem

The eighth meeting of the Israel Microbiological Society took place at the Terra Sancta College, Jerusalem, March 1949.

The meeting was opened by Prof. L. Olitzki, Head of the Department of Hygiene and Bacteriology at the Hebrew University, who reviewed the activities of the Israel microbiologists in recent years and the difficulties they had to overcome in challenging the mandatory government's policy of chaos. All laboratory services could be continued almost uninterruptedly, and, in addition to the existing laboratories, new ones were opened, particularly in connection with urgent matters, such as blood banks, Dr. Olitzki emphasized the future need of close contact between the laboratories and the government authorities in order to solve the most important problems of public health and to keep the standard of work as high as possible.

Friendly relations with the International Association of Microbiologists had been maintained. Twelve members from Israel were present at the International Congress in Copenhagen; five papers were read by them. One member, L. Olitzki, was appointed vice president of the Section of General Microbiology, and another member, M. Aschner, was appointed to the International Committee for Microbiological Nomenclature. An invitation to the next International Congress to be held in 1950 in Rio de Janeiro was received.

During the first session Dr. David Nachtigal demonstrated a method of cultivating smallpox virus in chick embryos. This method enables a quick differential diagnosis between typical cases of smallpox and varicella; the former produce typical microscopically visible vesicles on the chorioallantoic membranes, whereas the latter do not produce any pathologic changes.

Dr. B. Volkani (Weizmann Institute, Rehovoth) reported results observed in the metabolism of bacterial species with radioactive tracer substances.

The first part of the last session was devoted to serologic and immunologic problems. The diagnosis of syphilis, which was hitherto of minor importance, has now gained an important place among the laboratory methods. Serologic mass examinations of about 10,000 persons were carried out among immigrants before their departure for Israel and among Army recruits. The results obtained with quick methods adapted for mass examinations were reported by Drs. Rappaport and Eichhorn (Municipal Hospital, Tel-Aviv) and Dr. Gregman and Miss P. Gruenbaum (Kupat Cholim Laboratory, Tel-Aviv). Miss Skareton and Dr. Rappaport reported a quick method for diagnosis of infectious mononucleosis.

The last part of the session was devoted to the antibiotic substances. Dr. Rozansky and Dr. Brzezinski (Bacteriological Laboratory and Maternity Department, Hadassah University Hospital) reported on the appearance of considerable quantities of penicillin in milk of women in the course of treatment with this antibiotic. Dr. Raubitschek (Department of Dermatology, Hadassah University Hospital) demonstrated the antibiotic action of an aerobic spore-forming bacillus on pathogenic fungi. Miss N. Stybel reported the results of a survey of soil organisms carried out in the Hebrew University's Department of Botany under the guidance of Dr. T. Rayss in an extended area between Jerusalem and the Dead Sea. Antagonism was observed between different species of fungi.

### The First Diagnosed Outbreak of Q Fever in Israel

For the first time Q fever was diagnosed in this country. The diagnosis was based on the results of complement fixation tests with Coxiella burneti (Italian strain) as antigen, performed by Elisabeth and A. Klopstock (Tel-Aviv).

From 234 serum specimens so far examined 75 gave positive reactions in significant titers (1:32 to 1:2,048).

Nearly all cases occurred in Haifa. They were not confined to a particular section of the population or to a particular region of the town. About 80 per cent of the patients were male. Family infections were not seen. As the outbreak started in winter, ticks and other insects can be excluded as vectors. Direct contact with animals, especially cows and goats, is denied in the vast majority of cases. A possible source of the infection seems to be dust from packing material (straw) handled in the Haifa port. Most of the patients were not occupied or working in the port but went, as does nearly everybody in Haifa more or less regularly, near the port area.

As the outbreak has no explosive character but is protracted over several months, a persistent but as yet unknown source of the infection must be conceived.

The serum specimens which showed a negative reaction to the Q fever complement fixation test were mostly from cases of atypical pneumonia, not otherwise distinguishable from Q fever. A certain number of these showed cold agglutinins in significant titers, but others gave neither reaction.

### Hebrew University Hadassah Medical School

The Hebrew University Hadassah Medical School was opened on May 17 in Jerusalem. The first 50 medical students are beginning their studies in the new established classes, temporarily housed in the former Government Hospital in Jerusalem. On the occasion of the opening of Israel's first medical school, Prof. S. Adler, head of the Department of Parasitology of the Hebrew University, reviewed the unique situation. In the summer of 1947, Prof. W. Perlzweig came to Jerusalem to guide the University and the Hadassah. His visit was invaluable, and a deep debt of gratitude is owed him. If nothing untoward had happened, premedical education would or should have commenced in October 1948. All those plans were stopped by the disturbances and subsequently the open warfare against Israel. The Israeli Government called on all young fit Israelis studying abroad to return and take part in the defense. The response was immediate. Young men who had completed a part of their course left their studies and came over to fight. In many cases they could not, for various reasons, return to their medical schools, and they were faced with the grim prospect of having to abandon their chosen careers.

The Israeli army authorities, ever mindful of the interests of their volunteers, made a careful analysis of the whole situation and, together with the University and Hadassah, gave the soldier-students an opportunity to resume their studies.

The medical school is now an established fact.

## BOLIVIA

*(From Our Regular Correspondent)*

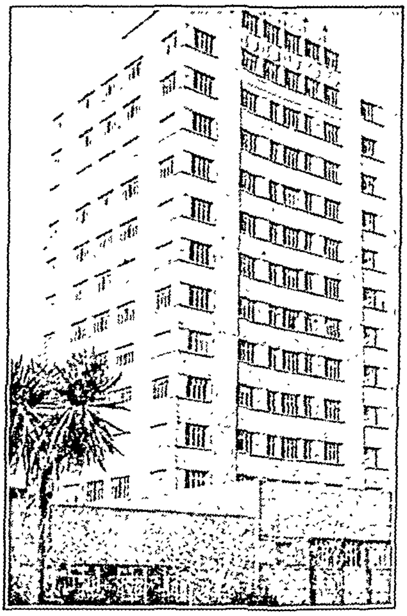
LA PAZ, June 29, 1949.

### Medical Meetings in Bolivia

The first meeting of Bolivian pediatricians was held at La Paz in May 1948, with some 30 physicians assisting. The most interesting paper was one on the study of weights and figures of infants. Widely discussed at this meeting also was the statement on infant mortality in this country, published by THE JOURNAL (136:417 [Feb. 7] 1948).

From October 19 to 23 the Fifth Inter-American Congress of Surgeons was held at La Paz; it constituted one of the brightest events of the simultaneous festivities in occasion of the four hundredth anniversary of the foundation of La Paz. The congress was sponsored by the president of the Bolivian Republic, Dr. Enrique Hertzog G., a well known physician in private life himself. Besides numerous Bolivian physicians, attending also were surgeons from the United States (Dr. E. P. Palmer, Phoenix, Ariz., and Dr. Hu C. Myers, Phillipi, W. Va.) who came representing the American College of Surgeons; numerous delegations from Argentina and Chile, as well as surgeons from Perú, Uruguay and several other South American republics. The three main subjects discussed were "Volvulus of the Sigmoid," "Fractures of the Distal Portion of the Radius" and "Hemorrhagic Infarction of the Bowel." Surgeons from most of the attending countries presented their papers on the subjects, and so did the American delegation. Dr. Palmer's paper on "Volvulus of the Sigmoid" was declared the best paper presented during the congress, a most important distinction. Dr. Palmer read also an excellent paper on "Fractures of the Distal Portion of the Radius," and Dr. Myers read one on "Hemorrhagic Infarction of the Bowel." There arose some question as to the exact meaning of the term "infarction," as several South American surgeons used that term for a clinical picture more closely resembling the over-all picture of spastic ileus. This question of the use of different meanings diminished somewhat the value of some papers on that subject.

Besides the main subjects, there were some twenty papers on free subjects, presented by Bolivian and other Latin American surgeons. There were also several meetings with the performance of surgical operations by the surgeons of the attending countries.



Building of the University of San Andres at La Paz. The Medical School is still located in a separate building.
